This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

NOTE ON
EPILEPSY AND ITS TREATMENT.

By SURGEON-GENERAL C. A. GORDON, M.D., C.B.,
Hon. Physician to Her Majesty the Queen.

The subject of epilepsy being somewhat prominent at the present moment, it is hoped that the following particulars having reference to it may not be devoid of interest.

With regard to the artificial production of the disease, Dr. Althaus wrote to the effect that a form of epilepsy may be caused in guinea-pigs which in some respects resembles human epilepsy, and has even been transmitted to the offspring of the animals; yet it has the tendency to disappear spontaneously, and is, after all, by no means the actual disease with which we are familiar in our patients (*Brit. Med. Journ.*, June 4, 1881).

Dr. Fothergill (*a*) writes: "Epilepsy consists of motor disturbances of the most varied character, from general and bilateral convulsions to a slight twitch, or the momentary arrest of consciousness, the *petit mal.* In each epilepsy there is an area of grey matter in some portion of the cerebrum, which is so abundantly nourished that it occasionally reaches very high tension and highly unstable equilibrium (Hughlings Jackson). He adds: The experimental researches of Ferrier corroborate the views formed *clinically* by Jackson. We can understand that the nerve energy stored up in cerebral cells may be discharged from some emotional cause, as fright, or from some irritation within the system, as a tapeworm or a decayed tooth, or still more, ovarian or uterine disturbance."

According to Dr. Radcliffe, (*b*) "Many of the facts which have been brought to light by the investigations of pathological anatomists are of little use in serving to fix the seat of epilepsy in any particular part of the nervous system. The changes in the cerebral hemispheres which have been found in epileptics who have also been idiotic, or fatuous, or lunatic, do not serve to fix the seat in these hemispheres, for these very changes are continually met with in idiotic, or fatuous, or insane persons who have not been epileptic. He is hopelessly at fault as to localisation, when he considers the exceptional cases in which, after death, have been found thickening of the bones of the skull, or the contrary, or exostosis, or ossification of the dura mater, or caries, or ulceration, or abscess, or tubercle, or malignant or other tumour, or aneurism, or embolism, or cysts, or atheromatous or ossified vessels, or hæmorrhage, or serous effusion, or sclerosis or softening of the brain substance, for the seat of these various lesions is as inconstant as their character. Nor is it possible to agree with Wenzel in fixing the site of epilepsy in the pituitary body, for Rokitansky says that he has frequently failed to discover any change in this body in those who had notoriously suffered from epilepsy and convulsion, and that he has met with it in others who were thoroughly healthy. Schrœder von der Kolk argues that the especial seat of epilepsy is to be found in the medulla oblongata. Dr. Brown-Séquard has shown that true epilepsy is producible in guinea-pigs by wounding the spinal cord in various places. Dr. Westphal invariably met with minute hæmorrhages in the spinal cord and cervical medulla in guinea-pigs in which a habit of epilepsy was brought about by hitting them smartly upon the head two or three times.

Dr. Lane Fox (*a*) considers that "in epilepsy there is much to be said about the vaso motor influence, although the opposite view has been taken by distinguished men. He observes that 'Meynert believes that in epilepsy the hippocampus major is a vaso-motor centre, irritation of which causes spasms of vessels, and so, epileptic convulsions. Nothangel considers vascular cramp an essential factor in all epileptic seizures. Binswanger says that in a typical fit excitement of the convulsive centre and of the vaso-motor centre are co-ordinated. Other views are indicated by Dr. Fox, all of which are in opposition to each other, as are those quoted above.

Dr. Porter wrote: "Much has been written about it; pathologists have sought in vain for any constant anatomical lesions, physiologists have devoted years to the artificial production of epilepsy in guinea-pigs, and still the disease remains enshrouded in the obscurity of 'functional disorders'" (*Med. Press*, April 29th, 1885).

Adverting to methods of treatment for the disease, and more especially to surgical interference, Mr. A. W. Buckland quotes (*b*) from Dr. Beven regarding many skulls belonging without doubt to the Stone Age, in which "holes of considerable size had been made evidently during life, as the wounded bone had become healed, proving that the trepanning had taken place at a very early age." According to Dr. Broca, epilepsy was the disease supposed to be cured by this barbarous operation. Mr. Buckland adds: "As epilepsy has in all ages been looked upon as brought about by evil spirits, it is regarded as proved that the early people who thus endeavoured to cure this terrible malady had a belief in spirits, and made this hole in the head of an inflicted infant in order that the imprisoned spirit might find a door of escape."

It is recorded that in the sixth century Alexander of Tralles, in Asia Minor, treated *epilepsy* by prescribing a piece of sail of a wrecked vessel to be worn round the arm for seven weeks. (*c*) Of the impostors of the day, Rhazes wrote: "Some of them profess to cure the falling sickness, and therefore make an issue in the hinder part of the head in the form of a cross, and pretend to take something out of the opening which they held all the while in their hands."

Coming down to the sixteenth century, namely, in 1527, the magnet was employed in the apparent hope of thus "drawing out" the disease.

Mr. Tait writes: (*d*) "The application of the trephine for the treatment of epilepsy is limited to cases where the disease is the result of injury to the skull. The first

operation of this nature was performed in 1705 by Guillaume Manquest de la Motte; it was repeated with complete success by Mr. Birch in 1804. Between 1804 and 1865 there are 50 cases on record (collected by Dr. James Russell, *British Medical Journal*, 1865). This paper of Dr. Russell's was published years before any of Dr. Ferrier's experiments were undertaken. Mr. West asks, "Are our indications in any given case, either of paralysis or epilepsy, sufficiently precise and well marked to warrant us in recommending the use of the trephine?"

Dr. Gowers has found that epileptic attacks often ceased, no matter what drug was given, and that no inferences as to the action of drugs in epilepsy could be drawn with certainty. Dr. Drewitt said it was the practice at the Children's Hospital to put a seton of silk at the nape of the neck. It seemed to succeed in many cases. Dr. Wilks agreed that almost any remedy or any other slight thing would arrest epileptic fits. He had known them arrested by toothache, fever, small-pox, &c. He was very sceptical of remedies. He had been taught long ago that setons were good in epilepsy; he had often used them, and found them valuable. (*a*)

NOTES ON

A CASE OF FRACTURE THROUGH THE BASE OF THE SKULL.

By D. JAMISON, jun., M.D.Ed.,
Newtownards.

I venture to give publicity to the following rough notes of a case of fracture through the base of the skull, as they may perhaps be of some interest as showing the long time during which the cerebro-spinal fluid sometimes continues to flow from the ear in cases where the fracture passes across the internal auditory canal, and is attended with rupture of the membrana tympani.

Some months ago I was called to see a boy who had been knocked down at a racecourse by a runaway horse. He alighted, I was told, on the side of his head, and was unconscious for some length of time.

A scientific agriculturist who was present suggested phlebotomy. and proceeded to operate by the somewhat unusual and unsanitary method of sucking the patient's nose. After having been aspirated in this infantile manner for some time, the patient became partially conscious and vomited. He was then put on a car and driven home, some six miles It was then I saw him. He was conscious but confused. Pupils unequal; face flushed; pulse quick; vomiting frequently. Vomit contained good deal of blood. Blood was coming from one ear freely, and there was great pain in the head. Ice was applied to his shaven head, and the usual treatment pursued. For the next three days the blood continued to drain away by the ear, and the pain continued in the head. One side of the face was more expressionless than the other, but there was no loss of power over the orbicularis palpebrarum muscle.

He was much troubled by a tickling cough which was evidently caused by blood passing down the Eustachian tube. It was relieved for a time by swallowing.

On the fifth day the blood ceased to come from the ear, but was replaced by a clear limpid fluid, which continued too ooze from the ear for the next nine days. During this time the patient was dull and stupid. He did not like to speak or to be spoken to. Was constipated and eat very little. Objected to light, and complained of loud noises in the head. On the ninth day from the first appearance of the clear discharge it stopped somewhat suddenly. From this on the patient improved rapidly. Two days after it stopped he wanted to get up, and said he felt quite well. I had great difficulty in persuading him to remain a few days longer in bed. His hearing is dull on the injured side, but otherwise he s quite well.

SOME

EXTRA-PROFESSIONAL EXPERIENCES.

By BRIGADE-SURGEON WILLIAM CURRAN,
Army Medical Department (Retired).

Being all my life a voluminous reader of books as well as a curious collector of those "wise saws and modern instances," medical and otherwise, that constitute the sum of human knowledge, or that conduce towards the realisation of that ideal of our race, the enlightenment and happiness of our brother man, I am induced to hope that such an occasional selection from these as circumstances may from time to time suggest would interest some at least of the readers of this journal, and that is, in a word, my reason for entering at all on this task in these pages. On mentioning the matter to the enterprising manager of this periodical, he, with that *aplomb* or insight that characterises him, understood my object even before I had half explained it to him, and believing with me in the truth of the Horatian maxim that—

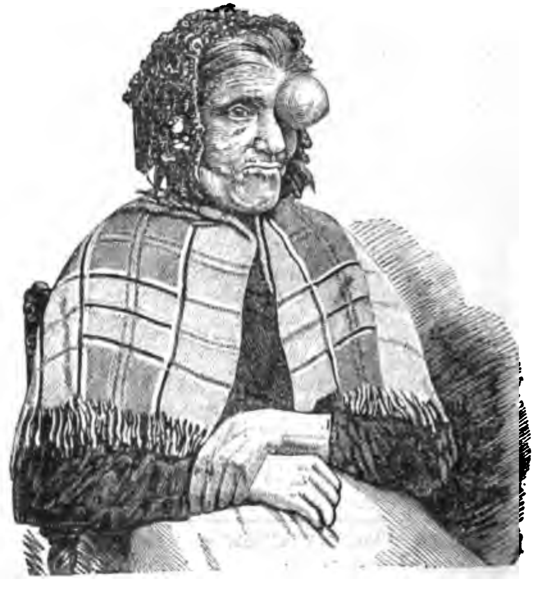
Segnius irritant animos demissa per aures,
Quamquæ sunt oculis subjectæ fidelibus—

he readily undertook the cost of any or such illustrations as may be required for their elucidation, or as I might be unable to supply myself. Whater merit, if any, may therefore attach to these effusions, largely, if not entirely, belongs to him. Mine is only the voice, or the pen—*vox et præterea nihil*—that ushers them into existence, and how feeble and flickering both these are no one knows so well as their owner.

Having ever cherished, like Bourdon, "a decided predilection and exclusive taste for pure and rational observation," I will refrain in connection with them from all speculative hypothesis and learned disquisition, and stick rather to simple narrative and obvious inference. I have no more sympathy with "Scotus the subtle, who clove a hair into sixty parts, and had marge to spare," than I have with him to whom "a primrose by the river's brim . . . a yellow primrose . . . nothing more." I heartily agree with Mr. Greville when he says that "there is always something to be learned from everybody, if you only touch them on the points they know." Influenced by these considerations, I have availed myself of such opportunities of acquiring information as chance or duty threw in my way, and the following are in brief the result and outcome of this somewhat promiscuous fellowship or Bohemian company.

Case I.—Fatty Tumour of the Forehead, the Growth of a Lifetime.

I have unfortunately mislaid the notes I made



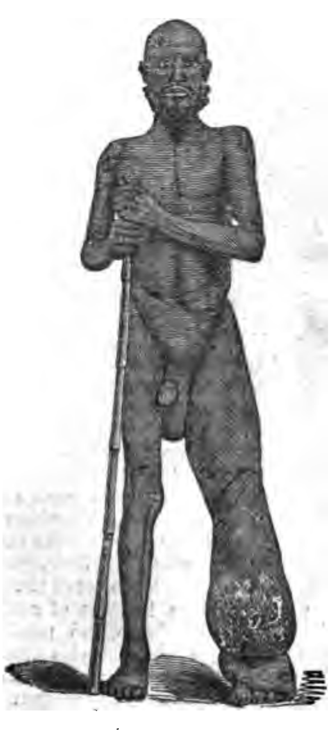
(*a*) *Brit. Med. Journ.*, Dec. 2, 1882, p. 1095.

of this case, but I have a very retentive memory, and the following account of it may be relied on. The subject of it—a woman of the working class—who resided near the Orford Barracks, on the outskirts of Warrington, was in fair general health when I first saw her. She was, she assured me, æt. 73 at this time, and, though of a feeble and wan appearance, she looked as if she would yet survive several years.

Struck with her appearance as I was passing her door one day, I stopped to speak to her and found, as I anticipated, that the tumour or swelling here indicated was, indeed, the growth of a lifetime. She was in short, she assured me, born with it, and it did not appear to incommode her much. I saw her several times subsequently, but, save that she appeared to grow somewhat paler or weaker than she was, there was no other material change in her case or in the calibre of this swelling. Having been away on leave or duty for some weeks, I inquired for her again on my return to harness, and was as sorry as I was surprised to find that she had died in the meantime. "She took to her bed, sir, soon after you last saw her, not caring whether she ever again left it or not," said her daughter to me on this occasion, "and she went out like the snuff of a candle," and, though I advised otherwise, she carried this excrescence with her to her grave. The sight of her left eye, which was, of course, habitually closed and through which she could only see when this tumour was raised, was, so far as I could judge, in nowise less than that of the other.

Case II.—Elephantiasis.

Wajid Ali, Mahomedan faqueer (beggar), aged about 46, single, says that he has been the subject of this disease since his birth. He enjoys excellent health and appears to be a man of equable temper and well-knit frame, but his left lower extremity is enormously enlarged, and exhibits a frighful prominence on its lower aspect, just above the ankle-joint. There has, however, been no increase in either within the last two years or more, and the condition would appear to have attained its fullest development. An attempt, that was made some thirteen years ago, to remove or reduce the protuberance just referred to, led to no result at the time, but he believes that its growth was subsequently stimulated by it, and its surface has been ever since broken and honeycombed. However well or ill-founded this impression of his may be, there can no longer be any doubt as to the propriety of leaving him alone, for his case admits clearly of no relief from surgical interference, and the following measurements will show at a glance the difference between the two limbs. These were carefully taken, under my own personal supervision, at Agra, in May, 1869, and there is reason to believe that he has since died.



Sound Limb.		Diseased Limb.	
Upper part of thigh	16¾ in.	Upper part of thigh	22 in.
Middle " "	15½ "	Middle " "	23¾ "
Knee-joint . .	12½ "	Knee-joint . .	17½ "
Leg just below calf	8¾ "	Over protuberance.	28½ "
Over centre of foot	9½ "	Over centre of foot	17 "

ATAVISM.

By GEORGE FOY, F.R.C.S.,

Surgeon to the Whitworth Hospital, Drumcondra; and formerly Lecturer on Anatomy and Forensic Medicine in the Carmichael School of Medicine.

It is the peculiar advantage of medicine that every advance in scientific knowledge ultimately benefits her. Even apparent abberrations of nature work for her good, and owing to her inexhaustiveness every aid is readily accepted, and quickly made to produce results. Being a science based on observation medicine suffers more than others from the inadvertence and death of her members. When we have full knowledge of a subject we find it not an easy matter to so clearly put the case, that the reader will, if of ordinary intelligence, rightly know what we wish to convey to him. Again, the influence of time and use on words is to alter their meaning, and this may so markedly occur, as in the case of the book of "Common Prayer," that words formerly the most suited to carry the writer's meaning, become misleading. And, if under the most favourable circumstances, error is with difficulty kept out; how hard is it to avoid error when we only partially know, and imperfectly describe what we see. Plainly, human imperfection keeps medicine an inexact science. The accumulated experiences of millions of men extending over centuries of time, some carefully and accurately recorded, and others evidencing too plainly haste and inaccuracy, all need interpetration, and ever and anon, comes some phenomenon of nature, like the Babylonian hand-writing, commanding attention, and defying the soothsayers and wisemen, a handwriting only to be read of the God-gifted.

With such divinely inspired sons medicine has not unfrequently been blessed, and like heaven's light the blessing has not been confined to one nation or one people. In almost every land the leader has arisen capable of leading and worthy of obedience, falling at last, after, have achieved much and guessed at many truths.

So died Jenner and Darwin, and dying left their half-solved problems as legacies and duties for successors that the exigencies of the time may call to take up the duty. That such men have not wholly succeeded should make all humble, and that such men had but taken up the tangled skin of fact and fancy as others left it should make all hopeful.

The farm servants had long observed the facts that led Jenner to his life-saving discovery, and every stock breeder was conversant with the influence of selection on cattle before Darwin undertook his great work.

To each of us in our time phenomena occasionally present themselves that if noted may furnish to some future worker the link necessary to complete his chain of evidence. How valuable to-day are the stories of the early navigators, and how grateful every anthropoligist feels for the collection of Richard Hakluyt.

And at no time was there ever a more earnest wish to learn the history of the past, and to preserve the records of the present than in this nineteenth century.

The reader has only to compare the carelessness with which the records of the rise of the Dutch republic were kept both by Holland and Spain, or the scanty historical records of the Commonwealth in England with the dilligence and care which our American cousins are so justly bestowing on the history of their Civil war. How prized now are the sketches of Winslow, Homer, and Edwin

Forbes, how precious the old photographs of many of those who are now buried in unknown graves. Everything tells us that what to day may appear trivial will possibly in time be a valued relic. Who of us is there that would not prize a Peruvian "tally string" or a Mexican "picture letter?" These considerations are my excuse for giving some particulars of a cleft-hoofed horse foal that was some time since exhibited in this city.

The foal was a horse, one month old, of a mouse colour, unstriped, well formed as to its head, body, and legs, but was peculiar in having its two fore feet and the off hind foot cleft. The near hind foot had a small claw like nail, curved, and closely resembling that of a dog.

The hoofs were such as ruminants have, though they were not used to support the weight of the body which caused them to project forward and be slightly turned upward, and the synovial sacks of the joint were swollen, and evidently pained the animal as he hobbled awkwardly along on the ends of the cannon bones.

The dam was about three quarters size, well formed, and had to the same sire borne a well-formed foal prior to the birth of this one.

The animal was foaled in Ballina in the co. Mayo, and was exhibited by its owner.

Cleft-footed horses are occasionally met with—twenty-five years since the stag-horse was shown in Munich. A description of the animal was given by Professor Flank, of the Veterinary College of that city. Bucephalus, the celebrated steed of Alexander the Great, is believed to have been cleft-hoofed. The occurrence of these abnormal forms press upon the naturalist the fact that hereditary predisposition may occasionally assert itself with such distinctness as to almost shake his faith in the scientific axiom that "animals are formed for circumstances by circumstances."

Here we find in the West of Ireland a foal possessing anatomical characteristics that show its ancestry with a race that successfully fought the battle for existence with gigantic reptilia in ages so remote as only to be measured by geological periods. Thanks to the labours of Marsh and Huxley the ancestry of the horse is well known.

Marsh's untiring zeal was well rewarded by the discovery of a series of fossil remains that enabled him to trace the gradual evolution of the horse from the lowest type to that form with which we are so familiar. To the series Marsh with poetic instinct gave the names, Eo-hippus, Oro-hippus, Meso-hippus, Mio-hippus, and Proto-hippus. From the first the gradual evolutionary change was continued without break, and from the small five toed, fox-like animal, and a simple enamel tooth layer, we see the gradual lessening of the number of toes synchronously with an elongation and strengthening of the middle finger, and an increasingly complex arrangement of the enamel layer of the teeth, transition changes as gradually and imperceptibly working as the fading of twilight into night. And so results "what has come to be, from what was."

The domesticated horse is as the utmost twig of a great family tree. He comes of a family that possessed the plasticity which made possible the forms of to-day. The social instincts of the animal remain unchanged though his anatomical form has so wonderfully altered. To-day on the plains of South America he exhibits the same gregarious instincts that characterised his remotest ancestors, as shown by the abundant fossil remains, on both sides of the Rocky mountains.

It is a strange commentary on the transitory nature of mundane conditions to reflect that in its native home the horse was so unknown, that the native Indian language possessed no name for them; how complete must have been their disappearance; how vast the interval of time that separated their last survivor from the foundation of the Kingdom of Montezuma.

For his disappearance we have nothing but conjecture. It is probable, at all events possible, that the intense cold of the Diluvium period drove the horse into the soft plains where his uncleft, narrow, hoof sinking in the soft earth, made him an easy prey to the flesh-eating animals of the plain.

We cannot, however, too carefully note slight causes, the slightest depression or depression of climate heats means the destruction or production of uncountable myriads of insects or the vegetation of region is transformed, and animals either multiply, migrate, or die out. In 1537 the Spaniards introduced horses into Buenos Ayres, and from a few animals that escaped the whole southern continent of America was over run by wild horses in 1580. On the other hand, we find that in Paraguay, a country over 90,000 miles in extent, an area greater than Great Britain, they were extirpated by a fly which found in the soft umbilical navel of the foal, a suitable place for egg deposition. A similar cause made the attempt of the French, in 1764, to acclimatise the horse in the Falkland Islands a failure.

Though America seems to have been the home of the horse, the fossil remains of the animal are found abundantly in the cave of Lunel Viel to the north of Lyons.

The history of the European species may be said to commence when the three-hoofed *Palœtherium Medius* was discovered by Cuvier. This animal, a dweller in boggy plains and marshes had his three toes on the ground, still the central one had already attained greater strength.

The next step in European ancestry is Anchi-therium, whose form less resembles the modern tapir than its predecessor, and whose teeth have become more suitable for vegetable diet. To the Anchi-therium succeeds the Hippariom, a more distinctly vegetable feeder, and whose lateral toes are merely rudimentary, not reaching the ground, and bearing no part in supporting the weight of the body. The size of the animal has become markedly increased, and from the size of a fox, the ancestors of the horse have reached that of the ass, and are fairly entitled to the name, donkey. It is from ancestry, such as a limited space, has allowed me to mention that the naturalist traces the occasional recurrence of inherited peculiarities in the horse, notably the tendency to cleft hoofedness. The persistency of inherited qualities cannot be better evidenced; the artist hunters of Languedoc pictured the horse, as we know him, on the ivory tusks of the Co. coal Mammoth, and Piétrement (1883) considers the long-headed horse of Solutré as having been treated as an article of food, an opinion not approved by Toussaint and l'Abbe Ducrost, who thought that, even at that early period the horse had been domesticated.

There is one strange circumstance about the evolution of the horse, that is that of all the pre-historic animals the horse alone increased by evolution both in stature and usefulness. Commencing in insignificance he in time commands the admiration of poets and even illustrates, by his perfection of form, the beauty and strength typified by Job. Attempts to date his domestication are but idle guesses at truth. In the days of Joseph Pharoah had chariots and horses. M. Patermost has, indeed, decided that our Aryan ancestors had domesticated the horse 9,300 years before the Christian era. A statement about as absurd as that of Abd-el-Kader, that Abraham was the first tamer of the horse. Whose was the triumph that subdued this useful animal to the servitude of his fellow man we know not, how long the struggle; how difficult the task, we never can know. How much man has benefited, and how grateful man is for this great gift, words fail us to tell. Occasionally some heart breaks forth in gratitude, and a responsive chord is touched in the hearts of all hearers. To whom are we indebted for the wise counsel that selected the horse and dog for domestication. To quote M. Joly, "man has discovered, and turned to account in most of the animals he has subjected to his rule an instinct of sociability, existing with a love of independence, and predisposing them to domestication. Here, once more his intelligence created him king; his absolute authority was accepted in place of that of the chief naturally chosen by the head when still possessed of liberty." Townsend, however, ascribes to the dog the first place in civilising influence. (*L'Esprit des Betes.*)

How strong this controlling power, that after untold centuries, only developes its physical characters. May we not reasonably suppose that in the cycle of ages psychological phenomena as startling as anything that the physical world has produced may result, and genuises who may shape ideas, startling and strange, may, by their very eccentricity run the risk of receiving unmerited condemnation for conduct disapproved because unknown, and therefore unvalued.

◆

Clinical Records.

ST. BARTHOLOMEW'S HOSPITAL.

Case of Acute Nephritis (scarlatinal?) with Left Apical Pneumonia.

Under the care of DR. REGINALD SOUTHEY.

CHARLES H——, æt. 6, attending school, was admitted September 22nd, to Matthew ward, with general anasarca. Signs of left apical pneumonia, and passing but little urine which was of a dark beef-tea like colour. He made a good recovery in the hospital, and was discharged November 13th, 1882. He was a darkly complexioned and fairly well nourished boy. On admission his features were obliterated by a puffiness of the cheeks, lips (especially the upper one), and of eyelids. The legs and feet were largely swollen, with a deeply pitting œdema; scrotum was also enlarged, and his hands were pitted on pressure. Mental condition good, no drowsiness or vomiting. Skin dry and hot. A red slightly weeping surface surrounded the anterior nares. Tongue dry, and presented a slight brown fur. The tonsils were somewhat large, and the cervical glands also, but not tender. Over the lungs there was marked compensative breathing heard on the right side; also some impairment of resonance, and a tubular character of expiratory sound over the left suprascapular region. Heart impulse, diffused and forcible. First sound much prolonged; sounds clear. He coughed repeatedly. He had done so, his mother said, for a few days, and he complained of pain all over the chest. Pulse 12 deg., somewhat hard. Respirations 60. Urine sp.gr. 1015, acid, containing 2 per cent. of albumen, and a large quantity of red blood cells, blood casts, granular casts (large and small), and so-called epithelial casts. His history was given as follows:—He suffered from abscess in the neck when six weeks old, had measles when fourteen months of age, and whooping cough eight months ago, and had since had a very hard cough day and night. He had a fall on the head two weeks ago, and was laid up in bed for two days in consequence. From this he quite recovered, and remained fairly well until the present illness which his mother said commenced on September 17th. The day previously he was attending school.

On September 17th the mother noticed that the child was not well, and on September 19th swelling of the face occurred with failing of the appetite. The boy was chilly, said he felt sick, and complained of headache.

On the 20th the legs and feet were noticed to be swollen, that of the face being more marked, and he vomited his food. He had eaten nothing since the 20th. He had diarrhœa on the 18th, 19th, and 20th, and the quantity of urine passed was said to have greatly diminished on the 21st and 22nd. Ordered D.L. milk; balneum tepidum statim et deinde balneum vaporis, also haustus sodæ tart. effervesc.—ter die.

Sept. 23rd.—Very fair night. Takes food well. Bowels open loosely and frequently, but not largely. Passed about 18 ozs. urine in the night. Perspired, but not freely after the vapour bath. Tongue moister but still furred on the dorsum. Pulse 120. To have as much milk and water to drink as he would take.

24th.—Fairly good night; but rather restless and cried several times. Takes food well. Bowels open freely. Urine more abundant. Tubular whiffing sound and dulness over the left suprascapular region, also very coarse expiratory sound with rhonchus over the right lung. Ordered—Balneum vaporis, omni die, cataplasma senapis-lumbis. Postea cataplasma lini-lumbis—tertiis horis.

25th.—Very restless night. Tongue less furred. Mustard caused marked redness over the loins. Bowels open six times in last 24 hours. Perspired freely after the bath. Scrotum much more swelled with pitting œdema this morning. Passed but little urine during the night—the urine is very dark in colour and deposits a large black flocculent sediment. Ordered.—One lemon; pulv. jalapæ c. gr. xx.; mucilaginis, ʒj.; syrupi, ʒj.; aquæ menth. pip. ad ℥j.; secundis horis donec alv. respondeat.

26th.—Much better night. Perspired freely after vapour bath. Pulse 120. Bowels open freely. Drinks freely.

27th.—Restless till 3 a.m., since which time he has slept well. Very thirsty. No appetite for solids. Perspired but little after vapour bath. Bowels open once. Passed rather more urine. Pulse 123. Respirations 78. Crepitations on right suprascapular region, and less markedly tubular breathing then. Ordered.—Hst. sodæ tart. efferv. ℥ss., 4tis horis. Balneum calidum deinde oleum carbolatum (1 in 30) applic. Mucilaginis ʒj.; syrupi, ʒj. Aq. menth. pip. ℥ss., secundis horis donec alv. respondeat.

28th.—Passed a good night. Bowels open freely three times in the night, quite loosely. Take freely of milk. Passed more water. Pulse 108. Respirations 52. Ordered—Balneum calidum omni die.

29th.—Passed a good night. Takes milk well. Bowels open freely. Ordered: Potass. acetatis, gr. v.; liq. potassæ, ♏x.; glycerini, ♏x.; infusi. quassiæ ad., ℥ss., 4tis horis.

30th.—Sweated well after the bath. Bowels open three times in last twelve hours freely. Takes food well. Good night. Pulse 96. Respirations 40.

October 2nd.—Passed a fairly good night (after 4 a.m.). Takes food well. Bowels freely open. Albumen present in urine. Scrotum largely swollen. Feet still pit on pressure. Face still swollen. No ascites. Ordered: Pulv. jalapæ c. as before, p.r.n.

4th.—Ordered: D.L. Fish, chicken, broth, egg 1, claret ℥ij. Balneum vaporis omni die; rep. jalapæ mistur. p.r.n., also pot. citratis efferv., ℥ss., with syrupi aurantii, ʒj.; quartis horis.

5th.—Bowels freely open three times in last twelve hours. Sweated freely after vapour bath for a long time. A good deal of cough. Urine rather more in amount and lighter in colour and containing less sediment, and still a trace of albumen. Pulse 112. Respirations 32. Some dulness at right base behind. Almost normal vesicular breathing, with a few crepitations over the left suprascapular region.

7th.—Very good night. Takes food well. Bowels freely opened. Perspired freely after vapour bath. Water freely passed.

9th.—Tongue clean. Water more freely passed. Scrotum much smaller. Features almost natural, and legs scarcely pitting. Ordered: Rep. omnia.

10th.—Bowels open freely after jalap. Sweated well after bath. Water more freely passed.

12th.—Passed a good night. Takes food much better. Bowels freely open after the jalap. Tongue clean. Water freely passed. Perspired freely after bath.

16th.—Passed 27 ounces of clear amber-coloured urine collected during the last 24 hours; some also was passed into the bed. No albumen. Heart's impulse forcible, and radial arteries hard. No abnormal signs over lungs. Hears well. Bowels open freely yesterday. Perspired freely after bath. Coughs a little. Scrotum of natural size. Legs slightly pit. Urine has no albumen. Sp.g. 1023 acid (no albumen now for a week). Ordered: Minced chop instead of fish.

23rd.—Pulse 100. Respirations 30. Tongue clean. Urine has a very slight trace of albumen; it gives no guiaic reaction and contains no casts, but a few red blood cells are present. Ordered: Balneum calidum, alterne die, postea oleum carbolatum applic., also vini ferri, ʒij. ter die.

30th.—Bowels open freely yesterday (without the oil). Eats well. Good nights. Hot bath every other day, and after each bath to be rubbed with oil.

Nov. 1.—Doing well. Has been up six days. Urine has slightest trace of albumen sp.g. 1025, acid. No red cells or casts detected in the urine under the microscope. Discharged.

ACADEMY OF MEDICINE IN IRELAND.

PATHOLOGICAL SECTION.

Meeting held FRIDAY, DEC. 3, 1886.
The President, Dr. WALTER G. SMITH, in the Chair.

PARASITIC DISEASE OF LUNGS OF SHEEP.

Dr. HENRY BEWLEY said that in the lungs of several sheep which were examined lately in the Physiological Laboratory of Trinity College, Dublin, a number of whitish or grayish nodules were found scattered through them, varying in size from 1-16 to 1-8 inch in diameter. On microscopic examination these nodules proved to be caused by a small nematode worm, from 15 to 17 mm. long, and extremely slender. The worm lay coiled up in the interior of a mass of apparently dried purulent matter. This mass was surrounded by a zone of elongated epithelioid cells, arranged in a radiating manner round the central mass. The epithelioid cells were embedded in a delicate fibrous reticulum; and here and there large giant cells were seen. Around these radiating cells was a zone of small lymphoid cells, embedded in fibrous tissue, and arranged in concentric layers. Outside these cells, in some of the specimens, was healthy lung tissue. In others the nodules were surrounded by catarrhal pneumonia. The worms in these nodules have no reproductive organs, and are apparently immature forms of strongylus filaria—a nematode worm that inhabits the bronchi and trachea of sheep and goats.

The PRESIDENT remarked that animal pathology was becoming increasingly associated with human pathology.

Dr. MACSWINEY asked did Dr. Bewley look for this parasite in any other part of the tissue of the sheep? It would be interesting to know whether its *habitat* was confined to the pulmonary organs, or the parasite was ubiquitous.

Dr. PURSER said it was difficult to suppose that the worm could have crept down through the animal's bronchial tubes. It was possible that some might have got into the lungs from the blood. They might have been swallowed, and might have bored their way out of the stomach into blood-vessels, and have been carried up to the lungs in that way. There was no difficulty in supposing that certain parasites would be in the lung and not in other parts of the body, because it was well known that different parasites had different tastes as regarded their places of living in the body.

Dr. BEWLEY, in reply, said he did not examine any other part of the sheep's body for parasites. He would have liked to examine its trachea, and he hoped to be able to do so at some future time.

STRICTURE OF THE ŒSOPHAGUS.

Mr. EDGAR FLINN exhibited the œsophagus and stomach of a man who died in St. Michael's Hospital, Kingstown, from stricture of the œsophagus, due to malignant disease. The history of the stricture dated back four years, the act of deglutition becoming more and more difficult during the last three months of the patient's life. The stricture became very much contracted during the last three weeks of his existence—so much so that he became unable even to swallow fluid, and had to be fed by nutrient enemata. A post-mortem examination was made, and it was found that the left lung was very much atrophied and collapsed. The walls of the œsophagus were greatly thickened and surrounded by a hardened mass matted together, which implicated the neighbouring structures. The œsophagus was very much narrowed at its lower fourth, and the most contracted part of the stricture was found to be about three-quarters of an inch from the cardiac orifice of the stomach, and would hardly admit of a small-sized pen-handle being passed through it. The stomach was enormously dilated—so much so that when the abdomen was opened it appeared to fill up the entire cavity, and was full of a brownish fluid, very offensive in odour. A large fruit stone was found immediately contiguous, and somewhat beneath the pyloric orifice, imbedded in a diverticulum. This fruit stone must have lain in this diverticulum for a long time, the post-mortem appearances showing that its passage through the œsophagus would have been well-nigh impossible during the last two years of the patient's life; from its position near the pylorus, it exercised a considerable deal of pressure on the pyloric orifice, and thus, in great measure, the great dilatation of the stomach was to be accounted for. The liver was likewise very much enlarged. Dr. M'Kee, the Curator of the Royal College of Surgeons in Ireland, had made a microscopic examination of the parts, and had reported that the disease implicating the œsophagus was epithelioma.

The PRESIDENT remarked that the site of the disease in this case corresponded with that which was most common in malignant disease of the œsophagus—namely, the lower part of it.

Dr. WRIGHT said that this man had been under his observation for seven years, and there was not a month during which he was not once or twice at the dispensary with him. On the first occasion on which he saw him he suffered from albuminuria, and all through, up to a year ago, his urine when boiled gave a deposit of one half of albumen. Seven years ago he suffered from a severe attack of general anasarca, for which he was successfully treated in St. Michael's Hospital. The first intimation that he had of anything being wrong with the man's stomach was about five years ago, when he came to the dispensary complaining of gastric pain and severe hæmatemesis. On several occasions afterwards he had severe hæmatemesis. For three or four months there was no stricture of the œsophagus, and then suddenly the stricture developed. That was four or five years ago. It then came on spasmodically. For days he could with difficulty swallow milk; and then the stricture would yield, and he would be able to swallow solids without much difficulty. The case was rather an obscure one, and the number of opinions held about it was amusing.

Mr. DOYLE asked did the patient show any symptoms of old pleuritis?

Dr. BALL said one of the most interesting features in the case was the presence of the diverticulum in the pylorus. True diverticula were exceedingly rare. Mr. Moore, one or two years ago, brought before the Pathological Society of London a case of several true diverticula in the neighbourhood of the pylorus; and he suggested that they might be analogues of the multiple diverticula which were present in fishes. He (Dr. Ball) had not examined the present case sufficiently to see whether there were smaller diverticula in addition to the larger one which contained the fruit stone.

Dr. PURSER said the most interesting point in the case was the dilatation of the stomach. In stricture of the œsophagus the stomach was usually contracted. There must have been some disease in this patient, long before the carcinoma of the œsophagus, which produced the dilatation of the stomach. It appeared to him that the pylorus was extraordinarily small. The stricture of the pylorus must have been either produced by disease or congenital. The pouch in the stomach was, he thought, not an abnormality, but the product of the fruit stone in its ineffectual efforts to get through the narrow pylorus.

Mr. FLINN, in reply, said he was not aware that the patient had had pleuritis or any affection of the chest at a previous date. He did not think there were any diverticula except the one where the fruit stone was.

ADENOMA FROM THE MAMMARY GLAND OF A RAT.

Mr. J. A. SCOTT exhibited a specimen of adenoma from the mammary gland of a rat; at the Carmichael College of Medicine a number of rats were kept, the one from which the specimen was taken was brought to him by the porter. It had a big tumour in its abdomen, into which its legs seemed to be drawn up, very much in the way in which a penis sometimes was into a large hydrocele. Nevertheless, the animal had been several times pregnant, and was able to suckle its young. The rat was killed, and on opening it he found the large tumour which was before them. A section of the tumour showed it to be an ordinary adenoma. A part of the specimen showed the ordinary excretory mammary gland, with a quantity of fat; in other parts there was the gland tissue, and elsewhere a large quantity of fibrous tissue.

The PRESIDENT.—Did you ever observe any similar case amongst your numerous family of rats before?

Mr. SCOTT said he had invariably opened the dead rats, particularly the females, in order to secure the embryos, but he had never before met with a tumour of the mammary gland in any of them. He did meet with an ovarian tumour, and he hoped to bring it before the Section. He believed the late Dr. Harvey found something of the sort, but the bottle containing the specimen had been lost.

SIMULTANEOUS FRACTURE OF BOTH CLAVICLES.

Dr. E. H. Bennett submitted a cast exhibiting this lesion, taken from a man who was treated in Sir P. Dun's Hospital, and also the clavicles of a little girl, æt. 6, who had sustained a complete fracture of one clavicle, and an incomplete fracture of the opposite, by being run over by a tram-car. Having detailed the history and mechanism of the injuries, Dr. Bennett directed attention to the fact that in the first case perfect union had been obtained in both fractures, with but little deformity—a fact of importance, seeing that out of eighteen cases collected by Gurlt, no less than eight had resulted in non-union of the fractures—a result clearly attributable to the difficulty of maintaining the parts at rest in such an injury without the very most careful nursing. Dr. Bennett exhibited at the same time a series of injuries of the costal cartilages taken from the body of the child who had had the collar bone broken. On the right side, the second, the third, and fourth cartilages were broken transversely, while the first was dislocated from its rib. On the opposite side one of the lower cartilages had been also dislocated from its rib, and one had sustained a partial fracture. Dr. Bennett directed particular attention to the dislocation of the cartilages from the ribs, as the occurrence of such dislocation had been denied by Malgaigne. He also directed special attention to the incomplete fracture of one of the cartilages, not on account of any great practical importance attaching to the injury, but as serving to complete the analogy between these injuries and fractures of bone.

Dr. MacSwiney asked did Malgaigne, in his criticism, or rather dogmatic statement, that dislocation of the cartilage never occurred, refer to adults or children?

Dr. Ball said that Dr. Bennett's first case was in Sir Patrick Dun's Hospital under his (Dr. Ball's) care, and they had considerable difficuly in keeping the fragments in place; and very probably there would not have been any union of them at all but for the kindness of other patients in the ward, one of whom frequently gave the man a smoke.

Dr. Purser said that he could not see anything *à priori* absure in the separation of the cartilage from the bone, particularly in children. He would suppose that injury more apt to occur in children than in adults. The point where the growing cartilage joined the bone was rather a weak place. The cartilage itself was softened, and the new bone, where it developed into a cartilage, was very slight, so that it would be very easy for such a separation to take place in children. Dr. Bennett had made a fine distinction between the separation of the cartilage from the bone and the separation of the cartilage leaving a little bit of it in the cup. There was nothing peculiar in the cup, for when ossification was advancing periosteal ossification advanced along with the cartilaginous, and the fracture was the same thing whether it was scooped out from the cup or broken across. He rather wondered that the injury was not more common in young children, and that the movements of a child were not sometimes enough to tear off the periosteum.

Mr. Flinn mentioned that about eight years ago a case came under his notice of a coal miner, in Staffordshire. While engaged in a lying position in what is called "holing," a very large piece of coal fell on him and fractured both his clavicles, which subsequently united,—the one at the sternal end and the other at the acromial end. The lower third of his femur was also fractured.

Dr. Bennett, in reply, said that Malgaigne gave four cases of this fracture at the age of seventeen, which was the earliest age that he recorded. It was an eminently difficult thing to keep it reduced, for, although after the individual had made a full breath the parts would slip into their places, when the chest collapsed they would slip out again.

CEREBRAL MENINGITIS AND ABSCESS.

Dr. Quinlan exhibited a case of cerebral meningitis and abscess. He said it was taken from the body of a scrofulous, starved-looking young man, æt. 23, who was admitted into St. Vincent's Hospital on the 23rd November. He had for many months had an offensive purulent discharge from his right ear, and was on admission suffering from the most agonising pain, radiating from the ear to the frontal, parietal, and occipital regions. His pulse and temperature were above normal, but he was quite clear in his mind, and had no convulsions or muscular stiffness. On the morning of the 25th November, about 8.30 a.m., he become suddenly stupid and heavy, and the right pupil became dilated and insensible to light, the left pupil remaining normal. He gradually got comatose, and died at 2 p.m. A post-mortem examination was made twenty hours after death by Mr. Coen, the house surgeon. The dura mater was firmly attached to the upper part of the brain, the general surface of which was rather congested. On removing the brain a dark discoloration was perceived on the side of the right middle lobe, and on the back part of the cerebellum and on the medulla oblongata a large patch of recent meningitis with subarachnoid effusion. On opening the right ventricle it was found full of sero-purulent fluid, and on making a section of the right middle lobe a large abscess, full of offensive pus, was discovered, corresponding to the dark spot already mentioned. The petuous portion of the temporal bone was extensively diseased; and the cause of the sudden coma on the day of death was, no doubt, the bursting of the cerebral abscess into the right ventricle.

Dr. MacSwiney said the pathological symptoms in the case were those of chronic purulent inflammation of the middle ear. He wished to ask what was the condition of the temporal bone and the bones of the ear on the side affected? Was the disease obviously extended from inflammation of the middle ear?

The President.—Was an examination made of the petrous bone?

Dr. Quinlan, in reply, said there was an opening into the petrous bone, from which matter was flowing. He probed it and found the bone quite diseased and disorganised, but he did not cut the bone out. There was the same smell from the pus that came out of the ear as from the pus that came out of the abscess.

The Section then adjourned.

◆

LIVERPOOL MEDICAL INSTITUTION.

48th Session, 1886-7.

The fifth ordinary meeting was held on December 9th.

The President, Dr. Nevins, in the Chair.

Dr. E. W. Hope read a paper on

INFANTILE DIARRHŒA.

Reviewing certain features of the disease as they presented themselves in Liverpool. It was shown that notwithstanding the great increase in the population, the deaths from diarrhœa, like those from fever, had steadily declined during the last twenty years. The unequal incidence of the disease upon various districts of the city, admitted of a partial explanation by the preponderance of poor and squalid inhabitants, in one locality over another, and by the bad condition of their dwellings and general surroundings. These points, together with others, bearing upon the great annual and seasonal fluctuations in the mortality from diarrhœa were fully illustrated by statistical tables. With regard to the domestic aspects of the question, Dr. Hope gave the results of his personal investigation into one thousand fatal cases of the disease, noting the mode of feeding, age, nationality, condition of dwelling, legitimacy, and other circumstances which were likely to have affected the infant. A fair approximation to the number of infants fed in each particular way had been arrived at by extended inquiry, and it appeared from the tables which illustrated the paper, that the diarrhœa mortality of infants under three months of age, fed wholly or partially on artificial foods, is fifteen times as great as amongst breast-fed infants of the same age. The desirability of avoiding the selection of the autumn months for weaning, was pointed out. Incidental questions, such as the insurance of infant lives, were briefly referred to in the paper.

LIVER FROM CASE OF MELANÆMIA,

Shown by Dr. Gemmell for Dr. Barron.

This specimen was obtained from a case of melanæmia, admitted into Dr. Water's Wards at the Royal Infirmary in the end of October. The patient, a seaman, about thirty years of age, was attacked with ague at Savannah some weeks previously, but appeared to have recovered. When, however, his vessel came into cold weather on the voyage home the chills returned, and on arriving home he was admitted into hospital. On admission there was an irregularly high temperature with an earthy colour of skin and apparent jaundice. He also suffered from nocturnal delirium, and during the day was dull, stupid, and occasionally incoherent. The blood being examined showed pigment granules, free and in leucocytes, and melanæmia was diagnosed. About three days after admission the patient became comatose, and died in less than twenty-four hours. At the post mortem the organs were all found to be more or less pigmented, and the capillaries throughout the body were found to be lined with a layer of minute pigment granules. The piece of liver shown is of a dark slate colour, and under the microscope contains much granular pigment chiefly in the interlobular veins, and in the outer zone of the hepatic lobules.

DR. SEMPLE'S ATOMISING INHALER.

Dr. Barr exhibited this inhaler, and spoke of it in very high terms. The medicinal substance to be inhaled is mixed with a petroleum product or other suitable solvent. It is then finely vapourised into the receptacle of the inhaler, from which it can be easily drawn. The inhaler is manufactured by Messrs. Parker, Davis and Co., and sold by their agents, Messrs. Burgoyne, Burbidges, and Co., London.

CASE OF MUSCULAR SPASM RESEMBLING THOMSON'S DISEASE.

Dr. Barr exhibited a male patient, æt. 57, who for the last three years suffered from a spasm of the muscles of the legs in attempting to walk after he had been at rest. In a few seconds this passed away, and he was then able to walk fairly well, though he brought his heels down with a flap. There was no ataxia, no ankle clonus, and the knee-jerk was about normal. The electric sensibility and contractility were fair, though there was a marked disparity between the two legs. These muscles were not so rigid or in such a state of tonic spasm as in Thomson's disease. The muscles contracted, but their action was prevented by a simultaneous contraction of the antagonistic muscles. In short, there was an abnormal irradiation of the voluntary impulse, which caused a more widely diffused effect than was intended.

Mr. G. Gibson-Hamilton showed a case of

CLEFT OF THE PALATE, THE RESULT OF ULCERATIVE STOMATITIS.

The child was æt. 6, and four years ago had been a patient at the Infirmary for Children, where what corresponds to the intermaxillary bone had necrosed, and been removed, leaving a cleft which extended into the mouth for a considerable distance. The little girl had been refused admission to an industrial school until something was done for her, and Mr. Hamilton therefore proposed operating by the subperiosteal method in a few days. It was fashionable at present (he thought to say in all forms of cleft palate) that a well-fitting plate answered the purpose, as well as any operative interference, but laying aside altogether the question of efficiency and expense there was this point to be considered that the mere existence of a cleft, and the knowledge that the person is not a complete individual, had an important bearing on the mental condition and character of the patient in the future.

Dr. B. Blower showed a case of

IMPERFORATE EXTERNAL AUDITORY MEATUS (CONGENITAL).

He said the patient was a little girl, æt. 11. The left external auditory meatus, ends about half-an-inch from its commencement in a cul-de-sac, and upon feeling the bottom of this with a probe, it will be found that there is tone beneath the skin. There is also stenosis of the right meatus about half-an-inch from the commencement, it being hardly an eighth of an inch in diameter at this point, and there is also some otorrhœa. The child is, of course, very deaf, but she can hear the vibrations of a tuning fork when placed close, even to the left ear. The case was introduced to the notice of Mr. Stone, of Rodney Street, and he agreed with me that it would not be safe to operate in order to make a meatus to the left ear, although much might be done to the right by careful application of sponge, or laminaria tents. I am at present treating the otorrhœa by injections of quiniæ sulph. in solution, and blowing in iodoform powder.

The President said the Society was much indebted to Dr. Hope for presenting it with a paper on which so much time and care had been bestowed.

Dr. Carter remarked on the rapid improvement of the general health in Liverpool in recent years. The city was conspicuous for the marvellous change that had taken place in the death-rates from fevers and diarrhœa. Typhoid had, however, not declined in anything like the same proportions as typhus, even if it had diminished at all. Closer inspection of houses in course of erection with regard to drains was necessary, and certificates that they were properly connected, or certificates of efficiency on the part of the plumber, the same as amongst ourselves. The attention of the Legislature should be drawn to the terrible fact that there were so many deaths amongst children whose lives were insured.

Mr. Blower thought it necessary that something should be done to prevent the deaths of insured children. Before death took place, however, there was difficulty in compelling people to feed their children properly, but after death an inquest might be insisted on.

Dr. Logan mentioned the strange prejudice there was on the part of mothers against giving cow's milk to children at the breast, the "two milks" being supposed not to agree. It was a prejudice that ought to be combatted.

Dr. Whitford thought a large proportion of the deaths were owing to infants having the "run of the house," in regard to food. With regard to insurance, he knew the case of a woman who had had five illegitimate children, they were all insured, and all died under twelve months. The woman lived with an aunt, and it appeared as if the woman was kept for the purpose of breeding children by whom money could be made through insurance of their lives.

Dr. Baily said that before the cotton famine in Lancashire children were given soothing syrups and bread and water, whilst their mothers were working in the mills. They were kept quiet in this way, and death soon ended their sufferings. But during the cotton famine, when there was no mill work for the mothers the infantile death-rate fell to one-fifth of what it was before. It had never again reached the former high figure.

Dr. Samuels thought all delicate children were insured, but not the healthy, and that children died from sheer ignorance rather than from more culpable causes.

Drs. Rawdon, Kelly, Archer, and P. Davidson also took part in the discussion.

Dr. Hope then replied.

The vacancies on the staff of the Belfast Hospital for Women and Children created by the death of the late Dr. S. M. Malcomson, and the resignation of Dr. Poole, have been filled up by the appointment of Dr. Hugh Lewers and Dr. Strafford Smith.

The Mortality of Foreign Cities.—The annual death-rates per 1,000 in the principal foreign cities, according to the last weekly returns communicated to the Registrar-General, are as follow:—Calcutta 32, Bombay 19, Madras 38, Paris 24, Geneva 22, Brussels 21, Amsterdam 24, Rotterdam 23, The Hague 26, Copenhagen 21, Stockholm 16, Christiania 19, St. Petersburg 24, Berlin 20, Hamburg 36, Dresden 21, Breslau 27, Munich 34, Vienna 25, Prague 28, Buda-Pesth 36, Trieste 32, Rome 25, Venice 28, Cairo 40, Alexandria 34, New York 28, Brooklyn 21, Philadelphia 21, and Baltimore 17.

Vital Statistics.—The deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 21·5 per 1,000 of their population, and were—Birkenhead 18, Birmingham 18, Blackburn 24, Bolton 19, Bradford 20, Brighton 11, Bristol 26, Cardiff 26, Derby 18, Dublin 28, Edinburgh 23, Glasgow 32, Halifax 26, Huddersfield 20, Hull 22, Leeds 24, Leicester 19, Liverpool 26, London 19, Manchester 29, Newcastle-on-Tyne 26, Norwich 21, Nottingham 20, Oldham 23, Plymouth 30, Portsmouth 21, Preston 31, Salford 21, Sheffield 18, Sunderland 20, Wolverhampton 30. The highest annual death-rates in these towns last week were—From measles, 2·1 in Cardiff, 3·5 in Leeds, 6·0 in Halifax, and 7·2 in Wolverhampton; from scarlet fever, 1·0 in Newcastle-upon-Tyne, 1·1 in Liverpool, 1·2 in Bristol, and 1·5 in Salford; from whooping-cough, 1·1 in Manchester, 1·2 in Bradford, 1·4 in Plymouth, and 1·8 in Huddersfield; and from "fever," 1·0 in Preston. The 35 deaths from diphtheria included 17 in London, 3 in Edinburgh, 3 in Portsmouth, 3 in Bristol, and 4 in Liverpool Small-pox caused no death throughout the United Kingdom.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 5, 1887.

THE NEW YEAR.

THE new year which is now upon us, pregnant with hopes and apprehensions as an offset to the enjoyments of Christmas time, is, on the whole, more promising than many preceding years from the medico-administrative point of view. Last year at this time we expected nothing, and our hopes so far have not been disappointed. This year, one's apprehensions have at any rate a tinge of hope. The constitution of the bodies which have for many years past presided over the destinies of medicine in this country has already undergone important modifications, and further changes are probable. In the three kingdoms a certain effervescence is to be remarked which is the prelude to conjunction among the local licensing authorities—a conjunction which it is to be hoped may in years to come take on a still greater extension. The difficult problem of accommodating rival interests is one which only the pressure of circumstances can solve, but this agent has so far been very fairly successful. Everybody who takes a genuine interest in the status of his profession must view with interest such measures as tend to educe order out of chaos, and which will protect each of the three kingdoms against the unbecoming and indecorous rivalry which at present characterises the competition of some of our numerous licensing bodies.

The question most prominently before the profession is as to the fate of the Societies of Apothecaries in England and Ireland. In both countries the Colleges of Physicians and Surgeons show a disposition to hold aloof from their humbler *confrères* the apothecaries. However much we might be disposed to sympathise with the feeling in the abstract, the bad effects of such exclusion on the interests the future of the profession lead us to deprecate the expression of opinion which, official in London, is apparently imminent in Ireland. By such refusal that unification of licences which it was the aim of the Act of last year to promote is to a large extent stultified, and the line of demarcation is accentuated instead of being obliterated. It remains to be seen how far the concerted action of members of the profession will be efficacious in remedying a state of things which was brought about, at any rate in London, in spite of and in direct opposition to, the expressed wishes of the profession.

A matter which concerns London students more particularly is the scheme, which has now taken unto itself a form, for providing them with a degree in medicine which shall place them on an equality with their provincial and colonial brethren. Opinions differ very widely as to the propriety of the resolutions adopted by the Royal Colleges of Physicians and Surgeons of England, but, on the whole, there is a very general feeling that something of the kind should be carried out.

Last year was marked by the laying of the foundation stone of the new Examination Hall by Her Majesty, and this year will probably be marked by its opening. Doubtless certain favoured entities are looking forward to that occasion as an opportunity of obtaining the titular distinctions which it may be the desire of Her Majesty to distinguish.

Prospects of reform at the College of Surgeons are fairly promising. The persistence and tact with which the claims of the Fellows and Members have been put forward have placed these claims on a firm basis, and have invested them with an authority which it will be difficult for the Council to ignore. It is, moreover, by no means impossible that the forthcoming year may witness a similar agitation on behalf of the ordinarily apathetic licentiate of the London College of Physicians. The action of the London Colleges in respect of the Apothecaries' Society has alienated a great many sympathies, and has given rise to a doubt as to whether bodies which respond so feebly to the wishes of the majority of their constituents are altogether to be trusted with new and extended powers.

Without partaking the opinion of Pangloss as to all things being for the best in this world, we have confidence in the general common sense of the profession, and we do not doubt that whatever measures may be taken and whatever reforms are achieved will be in the direction of a better and improved condition of things.

◆

PROFESSIONAL SECRECY.

THE subject of the relations which exist or ought to exist between medical men and their patients is one of very great importance. The responsibility which attaches to the fidelity and discretion of the doctor, the sick man's friend, has been a matter for serious consideration ever since—and possibly very much before—the days of Hippocrates, who laid down the golden maxim that whatever information was acquired by the doctor, in *or even outside* the exercise of his profession, was to be regarded by him as an absolute secret. This admirable part of an admirable code of ethics formulated by the illustrious father of medicine, has served to guide more or less his successors in the healing art. It has, however, been modified by law or usage in different countries, and since the circumstances are everywhere the same, the divergence of views and practice in this respect merit our very serious consideration. The Faculty of Medicine of Paris, as far back as 1599, resumed in a pithy formula the views then received: *Ægrorum arcana visa, audita, intellecta, eliminet nemo.* The maxim has from custom passed into law, and in most Continental countries the fidelity of the medical attendant—including nurses, midwives, &c.—is inculcated, and if need be, enforced, by laws which certainly do not err on the side of leniency. Considering the laxity of the laws in this country in so far as the obligation of secrecy is concerned, it is interesting and instructive to become acquainted with the views which obtain in other countries than our own. We venture to believe that as a general rule all needful discretion is exercised by members of the profession in this country, but it is quite open to argument whether the practice should not be made to receive legal sanction, and the authority of a duty, without which its observance is often quite impossible. What the law on the subject is in France is clearly and succinctly set forth in an erudite and carefully thought out treatise by Dr. Brouardel, the eminent Professor of State Medicine at Paris. Under the title of the "Secret Médical" he collates the clauses of the penal code and explains their bearing on cases which may occur and have occurred in practice. In France the obligation of secrecy is practically absolute, and no circumstance can warrant or justify the divulgation by the medical attendant of secrets. To this rule there are few exceptions, and these comprise a cognisance, whether acquired in the exercise of his profession or not, of plots against the State or against the life or well-being of individuals—cases of poisoning, ill-treatment of children, procuring abortion, or to save an innocent victim. The general principle which governs the exceptions is that the first duty of a doctor is to protect his patient, and if the patient is being poisoned, or, being a child, is subjected to ill treatment, then the doctor owes it to his patient to require the assistance of the law in saving him from further injury. When called upon to give evidence before a court of law, the duty of the doctor is to declare his inability to give evidence touching matters which he may have learned in the exercise of his profession *before taking the oath*, and according to a decision of the Court of Cassation, where the validity of the decisions of the lower courts is finally adjudicated upon, the professional privilege is absolute when the facts in question have been confided to him under the seal of his professional secrecy. Facts which have come to the doctor's knowledge during his attendance, but which have not been directly and deliberately confided to him, may be demanded in evidence at the discretion of the judge, who by his express authority relieves the medical witness of any responsibility in relation thereto. As a matter of fact, judges in France use their powers in this direction very sparingly.

Not very long ago Dr. Watelet, of Paris, conceiving himself injured by certain reports which had reached the public, wrote a letter to a daily paper, explaining his conduct in respect to the patient, then dead, in whose treatment he was alleged to have erred. His letter contained allusions to the malady from which the deceased had suffered, and although there was nothing in the revelations of a nature to injure or hurt the feelings of the relations of his patient, he was prosecuted for violation of the professional secret, and fined 100 francs. The law which obliges secrecy is rigorously enforced, and there can be little doubt that as a result there is less tendency to disguise the real facts of the case from the doctor who has been called in, and who is dependent to a large extent on the information afforded him by his patient as to the cause and nature of his complaint. Only last year a gentleman in Paris who, though married, kept a mistress, was shot from motives of jealousy by the latter, but contrived to reach home, explaining his injuries by a story of a nocturnal aggression. The medical man who was called in soon made himself acquainted with the real facts, and at once communicated with the police. His action, though it was not, so far as we are aware, made the subject of a prosecution, met with the almost unanimous condemnation of his *confrères*, and even in this country would probably have been viewed with disapprobation.

The only safeguard, as Dr. Brouardel points out, is for the medical man to lay down for himself a rule of conduct, not to be deviated from except under legal compulsion. Unfortunately—in our opinion—the legal compulsion in this country is construed to mean that evidence on facts in any way bearing on the case before the court, must be given as a matter of course, and judges persistently decline to recognise any particular privilege as belonging to our profession. The result must needs be in many instances an immense and often totally unnecessary exposure of facts which from their nature it were highly desirable, both from a public and a private point of view, to keep secret. Even wanton abuse of confidence here is only amenable to the common law, and no particular code declares what may and what may not with propriety be revealed. There would certainly seem room for improvement in this respect. While we are of opinion that it should be left to the discretion of the judge to order the violation of confidence in a certain class of cases where the information is absolutely necessary to a correct appreciation of the merits of the case, it is extremely desirable that the power should be used more sparingly and with more consideration for the feelings and interests of the parties concerning whom the information is required. Perhaps at some time in the distant future, when an attempt is made to codify our laws and reduce chaos to a semblance of order, our legislators may take advantage of the opportunity to remedy the *lapsus* left by the absence of specific injunctions. It is primarily in the interest of the public that reform is desirable, but it would also have a salutary effect on the relations of medical men with their patients, and would often save the former from painful situations in which his duty as a witness is made to clash with his duty to his patient. It would be interesting to know exactly what the general feeling on the subject is in the profession, and we should be pleased if our article were the means of eliciting expressions of opinion in relation thereto.

◆

THE CONJOINT EXAMINATION SCHEME FOR IRELAND.

The first report of the combined Committees of the Colleges of Physicians and Surgeons appointed to formulate a scheme for conjoint examination has been issued for consideration of the respective Colleges, and being in a semi-public condition, is open to criticism. We may with advantage give a brief epitome of the scheme.

For the present all information relative to the examinations under the Joint Scheme will be obtained from the Registrars of the two Colleges, either of whom will receive the applications and fees of candidates.

The examinations shall commence on the first Monday in April, July, and October with the Junior Grade.

The written examinations will be held at the College of Physicians, the oral and practical portions at the College of Surgeons.

FIRST EXAMINATION.

Candidates shall be required to produce evidence—(1) Of having been registered as medical students nine months before; (2) Of one course on Practical Anatomy, and one on Chemistry; (3) Of a course of Dissections; (4) Of a summer course on Materia Medica, and one on Chemistry; (5) Of three months' Practical Pharmacy.

Fees.—£15 15s.

TWO DAYS.—ORDER OF EXAMINATION.

First Day.—Written, on Physics, Chemistry, and Anatomy.

Second Day.—Oral, Physics, Chemistry, Anatomy, Practical Pharmacy. Fifteen minutes in each subject.

SECOND EXAMINATION.

Candidates must have passed the first exam.; also have attended—

1.—A Medico-Chir. Hospital for nine months, together with notes of at least three medical cases and three surgical cases.

2.—Winter Courses: Practical Anatomy, Dissections, Physiology, Surgery.

Summer Course (three months): Practical Physiology, including Histology.

Fees, £5 5s.

EXAMINATION (THREE DAYS).

First Day.—Written examination, three hours, on Physiology, Chemistry, and Materia Medica.

Second Day.—Oral. The oral examination shall be conducted at four tables, two examiners at each table.

Fifteen minutes on Anatomy, Histology and Physiology, Hospital Practice—Elementary Medical and Surgical, Materia Medica.

Third Day.—Practical examination in Anatomy, Histology and Chemistry. Anatomy: Each candidate shall make a dissection; half an hour being allowed for this purpose. He shall be then examined on that or any other dissected part. Histology: Preparations of objects under microscopes, and five minutes allowed to study them. Chemistry: Each candidate shall be examined in Practical Chemistry in the laboratory.

THIRD EXAMINATION.

Candidates must have passed the second exam.; also certificates of—

1.—A Medico-Chir. Hospital for nine months, together with notes of cases as in second year.

2.—Winter Courses: Dissections, Medicine, Midwifery, if not deferred to the fourth year. Summer Course (three months): Medical Jurisprudence.

Fees, £5 5s.

ORDER OF EXAMINATION (THREE DAYS).

First Day.—Written. Morning, three hours on Anatomy and Surgery. Afternoon, three hours on Physiology and Medicine.

Second Day.—Oral Examination. The oral examination shall be conducted at four tables, two examiners at each table. Fifteen minutes on Anatomy, Physiology, Medicine, and Surgery.

Third Day.—Dissections as in second year. Each candidate shall make a dissection of a region allotted to him, half an hour being allowed for this purpose. He shall then be examined on the anatomy of that or other dissected parts.

FINAL EXAMINATION.

Candidates must produce evidence—

(1) Of having been registered as a medical student forty-five months previously.

(2) Of third examination.

(3) Of having subsequently attended—

A med.-chir. hospital for nine months, as extern pupil; or six months as resident pupil; of having attended the following course of lectures:—

Winter Course: Midwifery, unless taken in the third year.

Certificates must be produced—

(1) Of having attended a recognised midwifery hospital, or maternity, for six months in the winter or summer of either the third or the fourth year, with evidence of thirty labours.

(2) Of three months fever hospital, and at least five cases of fever, to the satisfaction of the attending clinical physician, as attested by his signature.

(3) Of operative surgery in the summer of either the third or fourth year.

(4) Of clinical lectures in ophthalmic and aural surgery, three months.

Fees, £15 15s.

EXAMINATION (FOUR SEPARATE DAYS).

First Day.—Written examination. Morning, 3 hours, 10 a.m. to 1 p.m.—Medicine, Therapeutics (including prescriptions) and Pathology. Afternoon, 3 hours, 3 p.m. to 6 p.m.—Surgery, Therapeutics (including the writing of prescriptions) and Pathology.

Second Day.—Written examination. Morning, 2 hours.—Midwifery. Afternoon, 2 hours.—Ophthalmic and Aural Surgery, Forensic Medicine and Hygiene.

Third Day.—Oral examination—The oral examination shall be conducted at five tables, two examiners at each table. Twenty minutes in Medicine, Therapeutics, and Pathology, Surgery, Therapeutics, and Pathology, Midwifery and Diseases of Women. Fifteen minutes in Ophthalmic and Aural Surgery, Forensic Medicine and Hygiene.

Fourth Day.—Clinical examination.

Each candidate, before receiving his diploma, shall be required to produce evidence that he has attained the age of twenty-one years.

Certain salient points of the scheme are noticeable:—

a. The examinations will be thrice yearly instead of twice, as at present.

b. The first year will be a school year, and, as at present, a period which may be passed away from a teaching centre.

c. Note-taking is introduced as a necessary part of hospital study.

d. The courses of practical anatomy are reduced from three to two, and those on physiology to one theoretical and one practical.

e. The fourth examination is enlarged to four days, exclusive of operations, which we cannot find provided for in the scheme.

f. The student is to be allowed to pass through his studies and examinations at any age, but is not to go out into practice until he has passed his twenty-first year.

This scheme has yet to be discussed by the Council of the College of Surgeons and by both Colleges at large, not to mention the Medical Council. It would therefore be premature to discuss it.

◆

Notes on Current Topics.

Overhead Wires.

It is simply inexcusable that, notwithstanding the constant recurrence of accidents from the existing system of overhead wires, nothing has been done to remedy such a state of things. The more recent introduction of wires for telephonic purposes has largely increased the number of overhead wires, and although they have been fixed with every care, under certain circumstances they break and fall into the streets, to the detriment of Her Majesty's subjects and property. The destruction effected by combined wind and snow during the past week was probably greater in extent than any on record, and the comparative absence of accidents was due probably only to the fact that the inclemency of the weather and the hour of the night prevented anybody being about except those absolutely obliged to quit the comfortable fireside. Only one other course is open, and that is to lay the wires underground—an expensive process, no doubt, but one which is desirable not only on account of the exemption from accident which would be secured, but also from the fact that every little storm would not then entail widespread destruction of the wires and consequent interruption to the transmission of messages.

Certificates of Still Birth.

A medical man was lately fined £5 and costs for having signed a certificate of still birth for an infant which had lived a few hours. We can sympathise to some extent with the delinquent, seeing that such certificates are not generally credited with any great importance, and are the means of saving expense to people who are perhaps ill able to afford the cost of a formal funeral. Still the principle involved is important, and we hope that the example may serve to call attention to the illegality of a reprehensible, if common, practice. If a certificate be insisted upon from the medical attendant, it is incumbent upon him to be sure that it contains nothing inconsistent with the facts of the case.

Medical Students.

The third report by the statistical committee of the General Medical Council has just been published, containing a summary of statistics regarding medical students registered as beginning the study of the medical profession in the quinquennium of 1871-75. The investigation of the committee, for the successful prosecution of which they are greatly indebted to the registrar, Mr. W. J. C. Miller, has included the tracing of 6,403 registered students, of whom 4,472 were found to have gained a place in the Medical Register. The committee propose to elaborate their work by constructing a census of the profession at two selected annual periods, the years chosen for this purpose being 1881 and 1886. "In such quinquennial censuses," remarks Mr. Marshall (chairman of the committee), "many most interesting points will be cleared up, such as the strength of the profession, its distribution amongst the population of town and country, its fluctuations, its migrations, and many other details relating to titles, qualifications, age, mortality, and so forth. The construction of these censuses will be a comparatively easy task, as compared with that already accomplished. It will be undertaken by the same diligent and accomplished agents as we have hitherto had the advantage of engaging, and care will be taken to make the basis and outcome of the inquiry as sound and accurate as possible."

Fraudulent Drugs and Muddleheaded Justices.

The stipendiary magistrate for Sheffield has immortalised himself by a uniquely stupid series of decisions. A druggist was summoned under the Sale of Food and Drugs Act, at the instance of the Health Committee, for having sold tincture of opium which was not of the nature, substance, and quality of the article demanded. The medical officer of health proved that he purchased at the defendant's shop three ounces of tincture of opium. The borough analyst certified that the proportion of opium in the sample was less than one-third of that contained in the tincture of opium of the British Pharmacopœia. The facts were admitted by the defendant, but the stipendiary said that no doubt the action of the Health Committee was very laudable, but he was of opinion that if a preparation contained *any opium and any alcohol whatever* it could legally be sold as tincture of opium. Another shopkeeper was summoned under the same Act for having sold paregoric elixir, which, according to the certificate of the borough analyst, was "wholly destitute of opium, which was the most important ingredient of paregoric elixir." The vendor said that he supplied shopkeepers with the article complained of, so that they might not infringe the Pharmacy Act, they having no licence to sell poisons. He could not name any ingredient of a medicinal value that the paregoric without opium supplied by him contained. The stipendiary said the name "paregoric" failed to give him any definite impression any more than soothing syrup. It was pointed out that, for all the defence amounted to, they might simply sell coloured water, and call it paregoric. The stipendiary said he did not see that the law prevented it, and dismissed the case.

The Repeal of the C. D. Acts.

An edifying spectacle was offered—gratis—to the inhabitants of Plymouth on Friday last, when the whole of the patients of the lock wards of the Royal Albert Hospital, Devonport, were discharged into the streets irrespective of their condition as far as their malady was concerned. This, it was stated, was done in pursuance of the operation of the Act for the Repeal of the Contagious Diseases Acts passed some time ago, and no substitute of any kind has been provided. Nearly all the public bodies in Plymouth and Devonport have expressed opinions adverse to the present condition of things. Until the time arrives when public common sense will be sufficiently developed to override the silly qualms of a society of old maids the only proper course to pursue is to throw open the general hospitals for the reception and treatment of venereal affections. It is difficult to excuse the reluctance of the governing bodies of hospitals to receive such cases. The same general principle of Christian charity should operate in one case as in the other, and the victim of a drunken brawl is scarcely a more pity-inspiring subject than the woman of whom, in the language of a French poet, he has "demandé un baiser pour un morceau de pain." The effect on the public health from the disbanding of this *élite* at Plymouth cannot but be disastrous. A single diseased prostitute has been known to infect a whole village in the short space of a summer visit, and under the favourable conditions which necessarily prevail in garrison towns like Plymouth, a notable increase in the number of venereal cases may confidently be anticipated.

The Patent Medicine Stamp Act.

THE Inland Revenue department seems lately to have awakened to the fact that a great many preparations are being sold which could conveniently be included in the schedule of the Act. The proceedings which they have instituted in consequence have called attention once more to the vexatious and unjust nature of the tax which weighs very heavily on the consumers of the so-called patent medicines without a corresponding benefit to the Exchequer. Our contemporary the *Pharmaceutical Journal* has taken the matter up in the last number, and has re-edited the reasons which were brought prominently forward during the last year or two. When the matter was brought before Parliament it was promised that the question of its application should be considered, and apparently it has not got further than—if, indeed, as far as, this stage.

Jubilee Hall.

THE present year will probably witness the opening of the new examination hall on the Embankment, the foundation stone of which was laid last year by Her Majesty with regal pomp and ceremony. At present it is not exactly known what appellation is to be applied thereto, and we venture therefore to put forward the suggestion of a correspondent that the Hall should mark its date of opening by having affixed to it the name of "Jubilee Hall." It is true that the state of mind of the future generations of students may not be precisely in accordance with the proposed name at the time when an imperious mandate calls them within its precincts; but it will none the less very adequately represent the feelings of those who are learned or lucky enough to have passed the ordeal.

Illegal Practice in Ireland.

A CORRESPONDENT of a medical contemporary complains that in Ireland no attempt whatever has been made to put a stop to illegal practice. He says that throughout many towns in the west of Ireland "medical halls" are established. The reputed owners have no licence from the Apothecaries' Society. In some cases they are medical students, in others chemists' assistants, who come down to a western town, and in the most open and illegal manner start dispensing and prescribing medicines. The writer blames the Apothecaries' Company of Ireland for this, but with no just reason, because that Company never possessed the power which the London Company possesses of regulating medical practice. It can prosecute a man for representing himself as an apothecary, or for dispensing medicines if he is not a member of the Pharmaceutical Society, but cannot otherwise restrain him. The counter practice, of which the writer complains, is the result of the extension of the Pharmacy Act to Ireland, and it was anticipated as a consequence. The Pharmaceutical Society discourages it, but cannot prevent it. It, however, connives at the very objectionable practice of the widow or other representative of a deceased pharmaceutist continuing to keep the shop open by means of an assistant, and thus is afforded facilities for counter practice. Whenever the Irish Medical Association has found any unqualified person representing himself as qualified they have at once threatened prosecution and put a stop to the proceeding, but these cases are rare.

Dispensing by Scotch and Irish Licentiates.

A MEDICAL contemporary in its last issue, in replying to a correspondent, makes the remarkable statement that—

> "A licentiate of the Scotch or Irish College of Surgeons is not legally qualified to visit patients *and dispense medicines* in England. Such a person so practising in virtue of that qualification would be liable to prosecution for infringement of the privileges of the Apothecaries' Society, if that Society thought fit to authorise a prosecution."

This startling pronouncement is at direct variance with the 31st section of the Medical Act, which runs as follows:—"Every person registered under this Act shall be entitled according to his qualification or qualifications to practise medicine or surgery, or medicine and surgery, as the case may be, *in any part of Her Majesty's dominions*, and to demand and recover in any court of law, with full costs of suit, reasonable charges for professional aid, advice, and visits, *and the cost of any medicines* or other medical or surgical appliances rendered or supplied by him to his patients."

The words "according to his qualification" in the second line of this clause has been interpreted by some persons—but not, as far as we know, by any competent legal tribunal—as limiting the privileges of a licentiate in surgery to pure surgery, and of a licentiate in medicine to pure medicine; but, even if this view were correct, the surgeon would be entitled to charge for medicines and appliances essential for surgical treatment, and there is no limitation to that. We should be glad to find some precise legal authority for the opinion given by our contemporary.

WE regret to announce the sudden death from syncope at Sutton Coldfield, of Mr. Charles Barlow, M.R.C.S., Medical Officer for the Sutton District of Aston Union, Warwickshire.

THE library of the London College of Surgeons will be closed from Tuesday to Friday, the 4th to 7th of January, and on Friday, the 14th, for the purposes of the examinations. These will be the last occasions on which the library will be closed for examination purposes, as the new Examination Hall is expected to be ready by the end of March.

The Residency of the Armagh Lunatic Asylum.

This office has been filled by the appointment of a Dr. Graham, of Belfast, whose name had not even been heard of as a possible favourite for the office. Not knowing anything whatever either for or against Dr. Graham, we do not wish to utter a word of derogation of his competency, and we assume he is as fit for the residency of a lunatic asylum as any of a thousand estimable medical practitioners in Ireland. His official record does not lead us to believe that he has had any experience whatever in lunacy, or of the administration of a large public institution, but we presume his religion and politics were of a taking colour, and that he had some friends who knew some one who was related to some one who was acquainted with the Chief Secretary or the Lord Lieutenant. If the purpose of giving these appointments into the hands of the Irish Government is to enable them to pay off supporters or tickle useful religionists, the public and the lunatics must be content to suffer, but if the purpose be to secure an experienced and competent officer for the administration of the Asylum, it is, in our view, scandalous that those who alone possess the special knowledge of the work should be shoved aside to make way for a personal job.

Tea as a Cause of Sterility.

Dr. James Davies states, in the *Therapeutic Gazette*, that the Druidic College of the twelth century considered tannin the most potent of all the products of nature in producing sterility, and that tea-drinking, as practiced by the public, undoubtedly acts in the same direction.

The Irish Crown Representative in the General Medical Council.

For the seat vacanted by the recent death of Dr. Lyons it is understood that the claims of Sir William Stokes, President of the College of Surgeons; Dr. William Moore, Physician to the Queen; Mr. Bennett, Professor of Surgery in the University of Dublin; and Sir George Owens, an ex-Governor of the Apothecaries' Hall—are under consideration of Lord Cranbrook, the Lord President of the Privy Council, whose duty it will be to advise Her Majesty on the subject.

Degrees for London Students.

We spoke incidentally in our "Retrospect of the Year 1886" of the last act of the conjoined colleges in the matter of obtaining the right to grant degrees to London students. The resolution to apply to the Crown for power to carry the scheme into effect was carried unanimously after a discussion extending over two meetings, and we shall doubtless learn in due time, what are the views held by the authorities on this subject, which has for long been a theme for anxious and often angry discussion. The scheme has our cordial approval, though we must confess rather as a *pis aller* than on its own merits. We see no other practicable means of remedying the injustice which has been the portion of the metropolitan student, and under which he has had to smart so long. Unless the unfortunate attitude of the colleges towards the Apothecaries' Society should militate against the fulfilment of our desires, there really seems some prospect of the realisation of a carefully matured and long suffering project. We must not, however, be too sanguine. There is many a slip twixt the cup and lip, and many are the pitfalls which await the embryonic scheme on its way to completion. Not the least formidable are those which are contained within the provisions of the scheme itself. The details at present left in blank but which will have to be filled in before it can be approved, are so many and the principles involved, so important, that it will need much tact, judgment, and discretion before success will crown the efforts which have been made. One point on which absolutely nothing has yet been said, is as to the status of the new degree holder and as to his relation to the colleges. Will he form a category apart, with representatives on the councils? will he, and his fellows, be presented with powers analogous to those which belong to the graduates of most other universities? Again, we are anxious to know who will regulate the details of the conditions and examinations? Whatever is done, and however it is done, means ought and should be taken to secure the representation of the various teaching bodies in the metropolis. It would be a deliberate insult and a masterly stroke of bad policy to grant new and extensive powers without due provision for their proper employment yet no such guarantee can be obtained, unless the teaching bodies are represented. The problem is perhaps the easier to solve from the fact, that the councils of the colleges already include eminent professors from different schools, and by a very slight extension might be made to comprise delegates from the schools not so represented. For the present, however, we can only live and hope. When fuller information is forthcoming as to the details we shall be in a better position to judge as to their desirability.

School Gymnastics.

By special invitation of the Chelsea Divisional Members of the School Board, a large number of people met last week at the Beethoven Street school to witness an exhibition of Swedish drill by some of the female scholars. The proceedings were presided over by Lord Brabazon, and were followed with much interest and some curiosity. The peculiar aptitude of this description of drill to procuring muscular development is well-known, and it is sufficient to note that the girls evidently went through their work with gracefulness and enthusiasm. It is scarcely possible to overrate the value of systematic exercise of this sort to the physical well-being of children whose surroundings and habits for the most part are not of the pleasantest or the healthiest. The benefit accruing therefrom is recognised in better class ladies' schools, but the extension of the system to our national educational establishments, and especially to girls, is more recent, and marks a distinct progress in the matter of education, which to be complete should be physical as well as mental. Additional interest was afforded by the inspection of the school workshops, where the boys so disposed are taught the elements of the various handicrafts. The specimens of work which were shown furnished ample proof of the excellence of the method and of the practice.

Testimonial to Dr. Waters, of Chester.

It was fully to be expected that the profession would not permit Dr. Waters, of Chester, to pass away from his work as a medical reformer without marking, in some suitable and acceptable way, their strong sense of his devotion to their cause. Our advertising columns to-day contain the initiatory announcement of a movement in this direction well deserving of approval and support. Dr. Waters has not only fought a long campaign for reform, but has fought it to a successful end, and few can know or appreciate the amount of thought, labour, and money he has expended on it. We hope the profession will make their gratitude manifest in a material way, for a recognition of Dr. Waters' services is well deserved.

Army Medical Matters in India.

A considerable number of *Gazette* notifications in India have recently appeared, under which the several branches of the medical departments serving in that country are affected. Thus, the appointment of medical officers and of warrant officers to Station Hospitals, and to the Hill Stations will be made by the Surgeon-General of the British Forces, with the approval of the Commander-in-Chief. When medical officers are permitted to proceed on leave of absence out of India on medical certificate, the medical certificates and their applications for leave are to be submitted to the Adjutant-General through the Surgeon-General. The Government of India have decided to withdraw the ship *Imperieuse* from trooping service, and to fit her up for the reception of 200 sick officers and soldiers for a month's cruise in the Bay of Bengal, the authorities at Calcutta to supply the necessary stores and equipment, and to provide the vessel with medical staff and establishment. Should a medical officer in charge of a hospital have reason to believe that any article of diet or stimulant in the purveyor's stores is of inferior quality, a sample of the article is to be submitted for analysis, and if the result be unfavourable a board of officers will be called to survey the inferior articles. The attention of medical officers is drawn to existing orders which prohibit them from granting medical certificates recommending that public servants be transferred from, or excused from proceeding to any station on the score of health, and they are directed to confine themselves to the form of medical certificate prescribed by Government.

Dr. Alfred Meadows, of London, has been elected an Honorary Member of the Washington Obstetrical and Gynæcological Society.

We are requested to draw attention to the first list of subscriptions to the "Jacob Testimonial," which will be found in our advertising columns. The Hon. Treasurers' acknowledgements in response to the "Nowlan Appeal" will also be found in our advertising columns.

The annual sale is announced, of the Donegal Industrial Fund, founded in 1884, by Mrs. Ernest Hart for the encouragement in England of Irish Home Industries and the benefit of Irish workers. The sale takes place at Donegal House, 43 Wigmore Street, London.

The Science of Hanging!

Dr. A. E. Douglas, of Warrenpoint, sends us the following note of a case of suicide by hanging, to which he was called a few days since, and which displayed extraordinary determination and careful study of details on the part of the suicide:—Thomas Fegan, æt. 37, 5 feet 8 inches high, and 11 stone 10 lbs. in weight, was found on the morning of the 14th of December dead and hanging to the hurline of his own house, having previously murdered his wife and child, whose mangled remains were lying on the floor. The way he committed suicide appears to be as follows: He got on a table, and from that to a corner on the fireplace, where there used to be a hen-roost, as proved by the egg shells and lime on the right seat of his trousers; standing there he fastened the rope to the hurline, and then putting a fast loop (not a running knot) round his neck, threw himself down. As I found him the face was placid, the eyelids not closed, both pupils dilated, the right most so, tongue slightly protruding, swollen, and congested, as if bitten; a drop or two of bloody mucus dribbling from mouth and nose, hands not clenched, but hanging quietly at his side, blood only on the right palm; the rope (an ordinary cart rein) deeply imbedded in the neck, and the knot fully five inches from the throat. There was a hard lump over the second and third cervical vertebræ. The body was off the perpendicular, with the right foot flat on the ground, and the left on the seat of a four-legged stool that had been upset. Except for his foot being in a pool of blood, and a stain on his right hand, there were no noticeable traces of blood. He was fully dressed except his coat and shoes. The measurements are—length of rope, 6 feet 4 inches; drop, 5 feet 8 inches. No post mortem being allowed, I could not say if the neck was broken or dislocated, but if the rope had been a couple of inches longer I think he would have had to try again. I may add that he committed the murders with an ordinary hatchet.

The Dublin Hospital Commission.

A paragraph has appeared in some of the Dublin newspapers to the effect that the report of this Commission—to which we have recently referred—proposes to close the Richmond, Whitworth, and Hardwicke Hospitals and distribute the £7,600 a year which they cost amongst other Dublin hospitals. It is not improbable that this will be the recommendation of the Commission, but it will involve a serious question, how the medical and executive staffs are to be dealt with.

Dr. G. H. Melville Dunlop has been elected an extra physician to the Edinburgh Hospital for Sick Children.

We are requested to announce that Mr. Thomas Salt, M.P., has been elected to be the Permanent Chairman of the Commissioners in Lunacy.

We regret to learn that Dr. Spence, of Burntisland, near Edinburgh, met with a serious carriage accident last week, owing to the slippery state of the roads, one leg being broken and the other much injured.

Glasgow.

[FROM OUR OWN CORRESPONDENT.]

ANDERSON'S COLLEGE, GLASGOW.—A quarterly meeting of the Trustees of Anderson's College was held in the College Buildings, George Street, on Dec. 22. Dr. Andrew Fergus occupied the chair. The election of trustees to several vacancies was the first business before the meeting. There were appointed in the third (the artisan) class Messrs. Mark Bannatyne and James McKenzie, and in the eighth (the philosophers') class Dr. George A. Turner. Dr. Marshall Lang said that Anderson's College as a college would shortly die -it might re-exist in fragments—the medical school and the technical college would interpret a part of the idea, but it was certain neither would interpret the whole of the idea, and as an historical institution, and an institution unique, for he thought it was unique—Anderson's College ceases. It had had a very honourable career. It had been in Glasgow a kind of popular University; that was the conception of its founder, and a very magnificent conception it was. He hoped in the days to come the conception would be to a certain extent much more fully realised than Anderson's College could realise it. He thought from Gilmorehill there would be an attempt made—and he hoped a successful one—to fulfil the idea of a popular University, to bring the University more into touch with the masses of the people, the masses as well as the classes. What had occurred to him was that before they would depart from the scene it would be well that they should put on record the history of the College, so that it might remain as a souvenir of the past and an indication of what did a useful high work in its day. Sir Michael Connal gave a few reminiscences in connection with the early days of the College. The present session has been a fairly prosperous one. The governing body of the new medical school will be appointed in the course of next month, immediately after which appointments, steps will be taken to erect new buildings in the immediate vicinity of the University, unless there is some unlooked for delay the new premises will, it is hoped, be occupied next winter.

Correspondence.

THE "JACOB" TESTIMONIAL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Allow me to state in your journal that I shall be sincerely and heartily ready to join in promoting the above. I cannot forget the courteous reference to my candidature in an early number of the *Press*, and if later on a little heat was evolved in the course of the conflict, I can only say that, while recognising the right of combatants to fight with all their energies, limited only by the bounds of truth, yet when the battle is over no one will ever be more ready than I to shake hands and be friends again. I cannot presume to speak for my friends, to whom I again return my warmest, and, I hope, lasting, thanks, for generous support. Dr. Sparrow, who now thinks a general practitioner ought to have been selected, is good enough to state that it was perfectly clear from the start that the combat lay between the two Dublin candidates, and that the only object I could gain was to split votes, &c. I beg to assure this gentleman that it was not quite so plain to me, and even to numbers of others, as his statement would imply. I paid provincial men the compliment of believing that in the nineteenth century, the old woman's story was not going to be so oracularly repeated. I now invite the attention of those provincials to no less than three onslaughts made on their entirety within as many months.

1st. Under the new Conjoint Scheme of the two Irish Colleges all provincials are shut out of all share in clinical teaching. This is not only a great pecuniary loss, but it is even a grosser affront to their self-respect. It is no less a grivous injury to students, and after the astounding revelations of the Medical Council's visitors regarding our two Irish Universities only spirited opposition offered on the Medical Council to it cannot fail of success.

2nd. The Senate of the Royal University, as if to further emphasise its insulting scorn of the provincial profession recently promulgated a rule which excludes all Irish dispensary men and all hospital men who compound, through the aid of pupils, from the clear legal right to sign certificates of competency in pharmacy. This new rule (see *Press*, Aug. 25) deprives apothecaries of such rights unless these reside in a large town or hold appointments in some eighty hospitals.

3rd. The *Brit. Med. Jour.* of last Saturday week notifies another blow at us, for while heretofore we might give a certificate in that very "complicated operation" of vaccination, this is now to be taken out of our hands, and students —our own sons, of course, among the number—must go to a certain practitioner, who has just, at the instance of the Dublin men, had a nice little place (£600 a year only) made out of ours' and students pockets. Of course the pill is gilded, and it is pretended that it is necessary to enable some Irish doctors in England to hold the office of public vaccinators. I publicly demand proof of the correctness of that statement, and also why all other students are to be mulcted as they to a dead certainty will be for the sake of a few practising in England. Those latter can get the certificate they require at no greater expense. I further say that if such an insignificant procedure as putting three or four pricks in the skin is to require a special course of instruction, (with £3 3s. of course down) there is no reason why many other procedures which are really more difficult should not be taught by a special instructor and in a special course. Here is a nice vista for the student.

In conclusion, I have only to state that those who fancy that there are no provincial students to be defended can, if they like, see in the foregoing proof enough to the contrary. It is notorious that the late corrupt hospital commission, which deliberately shut out my evidence, are going to shut up one of the greatest of Irish clinical fields.

I am, &c.,
T. LAFFAN.

◆

GRADUATED MOUNTAIN CLIMBING IN HEART DISEASES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR

SIR.—Dr. Cullimore's remarks in your issue of the 15th December, again raises the question of the suitability of high climates for certain forms of heart disease. Although I would not go so far as to exclude every person with suspicious heart symptoms from the benefit of mountain air, I join with Dr. Cullimore in the general condemnation of recommending mountain heights for diseases of the heart and arteries.

Where a fatty heart is suspected, mountain climates would be beneficial, especially the colder altitudes of five thousand feet. With a suitable dietary consisting largely of nitrogenous elements of food the fatty condition of the cardiac fibres would gradually undergo changes, as they were gently trained to greater exertion and more satisfactory work. Fat deposited on the heart in conjunction with general obesity, I should not be disposed to exclude; nor simple muscular weakness of the heart which is merely a symptom of the constitutional state. Cardiac functional derangement scarcely perhaps comes under our inquiry, but if not associated with extreme nervous excitement or pronounced hysteria, would undergo improvement.

Now, when we discuss cardiac dilatation, hypertrophy, or affections of the valves, I am still inclined to adhere to what I said at the Harveian Society, and which I am gratified to see supported by Dr. Cullimore's experience, viz.:—that diseases of the heart or large vessels should be a contra-indication against sending persons very high up the mountains, although each individual case must be judged on its own merits.

The amount of information at my disposal as regards persons with heart troubles being benefited at 5,000 and 6,000 feet, is naturally rather limited, as I have always discountenanced their coming, but to lay down a hard and fast line against anyone availing themselves of the mountain climate who may have a minor heart affection, has never been my intention.

I have met with two or three cases of mitral insufficiency, here, which required treatment and then went on as usual. One case, also, of an ancient rupture of a valve (caused by violent running) I should be disinclined to form a decided opinion now, as to what valve or valves are injured. This case, however, is extremely interesting. On the occasion of each visit made to Maloja (6,000 feet) breathlessness and palpitation demand immediate treatment which is continued off and on for the first month, when everything goes on well again. In spite of singular irregularity of the pulse plenty of exercise is taken, skating, walking and tobogganing, &c., the Maloja pass being descended (800 feet) and remounted.

I can neither verify nor refute Dr. Oertel's theory that true affections of the heart can be remedied by graduated mountain climbing; but my experience has been that the general health and strength of a few of these sort of cases have improved greatly: at the same time it is right for me to say that I have not directed special observation to this subject in the way that Dr. Oertel has; and secondly, that I have always found graduated exercise in the mountains not only salutary for my cases of pulmonary troubles, but absolutely indispensible, for nearly every condition of ill-health which comes under my notice.

I am Sir, yours, &c.,
A. TUCKER WISE, M.D.

Maloja, Upper Engadine.
Dec. 27th.

THE PERILS OF FOOTBALL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As there have been several accidents of this kind lately, while the pathological results of these mishaps are either not fully ascertained or are not publicly disclosed, I venture to think that the post-mortem appearances that came, in one of these cases, under the cognisance of a friend, may interest some of your readers. I subjoin them here accordingly, and will only add that they are, so far as I know, quite authentic. Anyhow, I took them down from the dictation of the surgeon who made this examination, and it was on them that the coroner's jury that investigated this fatality based its verdict of "death from an accident in the football field."—"A small-sized man of 24, whose height was only 5ft. 3 inches, was stooping forward in a semi-prone attitude, with the view of seizing the leg of an opponent, a much larger or heavier man than himself, whom he wished to stop or throw, as he (the opponent aforesaid) was running towards the goal with the ball under his right arm. The latter, who was looking in another direction, and who had no thought of such an obstacle as he was about to encounter, struck the quasi-crouching figure of his adversary on the head, in the region of the vertex, with the lower third of his femur, and then fell heavily over him.

In other words, the force of the concussion was such that he—the stooping player—was thrown violently backwards on his back, and that the other—the running player—was (as it were) flung forcibly upon him. The latter's leg was quite benumbed by the force of this blow, and the prostrate man, who was not at first supposed to have been seriously injured, was found on a further inspection to be insensible. His breathing soon became stertorous, and he died within some twenty minutes or so of this accident. On section several hours subsequently, the veins opening into the lateral sinus were ruptured in five different places, but there was no rupture, or even laceration of the scalp, and the bones of the cranium remained intact. A layer of coagulated blood enveloped the brain substance like a night-cap, and on removing the mass itself *in globo*, the right occipital sinus was also found to be ruptured. The blood that had escaped from these holes or cavities had encompassed the medulla as well as the pons, but there was no coagulation in this neighbourhood; and I believe that the bullocks or other beasts that were knocked on the head, according to the "good old rule, the ancient plan" of our forefathers, exhibited, plus, of course, some extra frontal depression, very much the appearances here enumerated.

I am, &c.,
WM. CURRAN.

Literature.

NEW THEORY AND OLD PRACTICE IN RELATION TO MEDICINE. (*a*)

BEGINNING with the assumption that "Medicine is not a science, and never can be," while he is the best physician, according to our author, who to the largest experience adds the most extended knowledge, Dr. Gordon discusses diffusively in this essay a large number of those moot points of which our knowledge is—to put it as strongly as we can—very limited, but with which the practice of our somewhat conjectural art is more or less connected. This being so, there is and must be necessarily some uncertainty as to our diagnosis, as well as to our therapy, and it is only by the method of experience or the method of experiment that these our difficulties can be encountered or overcome. As we cannot all have the experience which comes out of age or out of observation at home and abroad, it needs be that we must fall back upon other sources of knowledge, and the best of these, or at least the one that most commends itself to professional acceptance, is that by the way of regulated experiment or scientific investigations. But our author sets his face against the former, while he gives us nothing but doubt and question, carping and controversy, instead of the latter, and herein lies, as we believe, the essential weakness of his platform and the incurable fallacy of his work.

Dr. Gordon quotes so many authorities including the *Globe* newspaper, the *Morning Post*, the *Rappel*, and, save the mark! the *Zoophilist*, in support of his own views or in disparagement of those of others, that it would be impossible for us to enumerate the half of them. It does not, however, appear that he has himself tested the accuracy or the authenticity of either of these extracts, and he seems to forget that newspapers are for the most part commercial speculations which are conducted by men who have no scientific training, and whose columns must be filled daily with more or less relevant or "regulation" "matter." They are not always exempt from partisanship, or endowed with infallibility, and a fool might as safely or surely go to Canosso for wisdom or a madman to Anticyra for sanity as a physician or a philosopher would trust for the truth about Koch or Pasteur to the pages of *L'Independant du Midi* or to the writings of Mr. Benjamin Bryan or of Miss Power Cobbe.

Yet are these the sources from which Dr. Gordon mainly derives his inspiration, and this fact would of itself alone preclude our having any more to say to this essay did we not think it possessed other and better features. It does. It contains a good deal of shrewd observation and pithy remark; it also contains many wise saws and some modern instances that admit of other and more fruitful application than is here given to them, and it contains above all promise of better work on the part of our author in the, let us hope, near future. Destructive criticism has ever been the forte of disappointed men, but Dr. Gordon is not a disappointed man; he is a C.B. as well as a physician to his Queen, and he has attained the highest rank bar one in his department that it is possible for him to achieve. We look for better work at the hands of our censor than is contained within the covers of this dubious and inconsequential essay. The author of it has the ability and the leisure to build up as well as to pull down; he is deeply read in the history of his art, and medicine has enemies enough outside her pale without being also assailed from within. It is in any case "an evil bird that fouls its own nest," and it is not always safe or wise to kick away the ladder by which one has ascended.

◆

BRUNTON ON INDIGESTION. (*b*)

As the Lettsomian Lectures of the Medical Society of London, to which some 79 pages of this interesting book are devoted, have already appeared in these pages, we need not dwell upon them at any length here. Containing as they do, however, many ingenious allusions to or explanations of the phenomena of dyspepsia and torpidity of the

---

(*b*) "On the Disorders of Digestion: their Consequences and Treatment." By T. Lauder Brunton, M.D., F.R.S., &c. London: Macmillan and Co. 1886.

liver, the use of purgatives, and the dietary of disease, they are eminently suited for the digestion of the young practitioner, and to their style and tone no exception can possibly be taken. Nor does our author restrict himself to these comparative speaking minor ailments; he discusses the graver complications or consequences of these disorders, and shows himself *in utrumque paratus*, equally at home in both. As illustrations in point we might quote his amusing description of a City dinner, as well as his dissertation on cookery as a moral agent, and he has thrown more light on the causation of headache, the meaning of emotional dyspepsia, and on the value that the artificial production of fat in the economy, *à la* Weir Mitchell, causes in and for the system than can be found, so far as we know, in any other contemporary work. But all the same, the book, which is made up of the various essays which this industrious gentleman has contributed from time to time to the *Practitioner* and other journals, does not readily lend itself to the requirements of the reviewer whose space is as limited as ours is. Moreover, many of these must be as familiar to our readers as they are to us, and the drawings or devices by which Dr. Brunton enforces his theories, or explains the action of drugs, or the manner in which albumen, or the other products of a destructive metamorphosis are found in the excreta, must be studied in order to be appreciated or even understood. The book, in short, must be studied in the closet rather than glanced at in the gig, and nothing that we could here say would enable our readers to dispense with its presence on their shelves. To those practitioners who minister to the ailments of the dyspeptic and the neurotic its guidance must be very great, for it is chiefly though not exclusively concerned with what may be roughly called the chylo-poetic viscera, and the nervous system, and the well-arranged index by which it is accompanied will enable the perplexed or busy practitioner to find a readier solution of the difficulties that are incidental to these constituents of the economy than we could possibly hope to offer or afford him. We think the book is a good one, and we believe that it may with advantage be added to the libraries of our *confrères*.

◆

TAYLOR ON RHEUMATISM. (*a*)

Beginning with the intimation that "the main object of this work is to give a fair explanation of the principles and descriptive (*sic*) of the practice of medicine is to prepare the reader for observing to the best of advantage (*sic*) the actual phenomena and symptoms of the various forms of rheumatism and *diseases in general*—(italics ours)—and the power of the alkaline treatment over it; in a word, *the power of remedies over diseases in their general aspects*"—(italics again ours). Our author proceeds to deal with the subject of acute rheumatism: its complications and treatment, &c., to the almost entire ignoring or exclusion of the important topics we have here underlined. We do not at all blame him for this, or say the subjects are even irrelevant to his general theses, we only point to the fact to enable us to say that, as this book is evidently a first effort, while it displays considerable capacity and painstaking research; its author should in any future edition of it that may be called for, endeavour to adopt a less involved style, or more logical arrangement, and above all to recast his periods as, while ceasing to be ungramatical (as they now are in many instances), they may become less enigmatical, or more intelligible. We do not say this from any ill-will to Dr. Taylor or from any prejudice against his work, and we are quite willing to admit that this contains much promise of an earnest and laborious future (particularly so in what he says about rheumatic delirium and coma, rheumatic pericarditis, and articular rheumatism, and also on the relations that exist, or are said to exist, between these conditions and Bright's disease), but what we complain of is that he has only raised up many doubts and difficulties without being able to lay any one of them, that his work is overlaid with fanciful theories or exaggerated descriptions of imaginary ailments, and, that it is quite impossible to deal with such matters as we have signalised above within the compass or in the connection he has laid down for himself. The subject of rheumatism, its complications, sequelæ, treatment, and relationships generally, is large enough for any one, the strongest and the wisest amongst us, but to add to its consideration such other big topics, even collaterally, as we have glanced at is to enhance tenfold the difficulty of the situation, and this is why we do not now go into any more detailed examination of the promising work before us. We may say, however, that the formulæ it contains are good, while the directions for giving or taking them are appropriate, especially so those relating to the administration of the salycin compounds, and the comparative tables at the end of the work are well arranged, and very useful.

◆

JESSETT ON CANCER. (*a*)

As a considerable portion of this book has already appeared in these pages we do not propose devoting much of our already too handicapped space to a discussion of its contents. Moreover, these do not strike us as containing anything that is either very novel or very original, and works on cancer are almost as numerous, and quite as empty, as are those on corns, calculi or gout. We can only therefore allude to a few of its leading features, and say generally that for those who require special information about the particular points or structures included in it, no better compilation—and our author makes no other claim—can be chosen. The historical portions of it are well done, so are the statistical tables it contains, and, as to the treatment advocated by Mr. Jessett, 'tis that of the complete, early, and free excision of the implicated structures that is now so universally insisted upon by all operating surgeons. Believing that there is always a dyscrasia in the blood of those who suffer from what may be called "irritative" cancer, our author leans to the hereditary influence as the causative agent that has led to this, and he is nowhere, so far as we can see, an unconditioned localiser of that disease. Whether this is his motive or not we are unable to say, but he rigidly deprecates the use of caustics, and if we except the opium and its derivatives he employs, he does not appear to us to set much account by drugs. As to the statistics, he adduces pro and con the operation of gastrotomy and gastrostomy, gasterc-enterostomy æsophagostomy, œsophagotomy, &c., &c., they are so discouraging as to be, to our thinking, all but prohibitory of these procedures. But we had better let him speak, as below, for himself, and add, on our own behalf, that were we, or those of our inner circle, affected with either or any of the disorders that indicated a resort to these measures, we would rather bear the ills we have and die in peace than incur the risks attendant on such manipulations, and live, it may be, a few weeks or days at the outside.

"Of the four recoveries from the operation (of æsophagostomy) one lived two months, one three months, one five months, and one sixteen months. The average duration of life in all the cases after the operation was forty-six days; but if, as Dr. Gross remarks, the case which lived sixteen months be excluded, on account of the uncertainty of the true nature of the disease, the average life will be reduced to twenty-nine days. . . . In thirty-seven cases (of cancer of the stomach) that have been performed by different surgeons, twenty-seven died from the immediate effects of the operation (of excision of the pylorus). Czerny performed four pylorectomies, two of which died as the immediate cause (*sic*, effect?) of the operation. Billroth had three fatal results out of eight cases, and only one appeared suited for the operation out of the fifty or sixty cases (of the disease) he has examined." Save, oh! save us from such surgery is our earnest prayer and only comment on such statistics!

◆

ELEMENTARY BANDAGING. (*b*)

This unpretentious little volume is, we are told, only a reprint of certain portions of "Surgical Handicraft," but for its size the amount of information contained is really surprising. The directions for applying bandages *secundum artem* are copious and precise both in the matter of the text, which is clear, and of the illustrations, which are numerous. The use of splints is explained diagrammatically and otherwise, and full instructions are given as to the

proper course to pursue in the commoner casualty cases which may present themselves for treatment. We can cordially recommend this little book as a veritable *vade mecum* of surgical exigencies, which from its size and completeness is peculiarly adapted for the use of both students and practitioners.

◆

WEST ON CHILDREN'S DISEASES. (*a*)

THIS latest work of Dr. West is primarily addressed, as the title implies, to mothers. It differs, however, from many books similarly addressed, in being no mere guide to the conduct of the nursery, Still less does it profess to make every woman her own child's doctor. It rather ushers the mother into the confidence of her medical adviser, and sympathetically explains to her the *rationale* of more obvious symptoms and anticipates possibilities in a way which an intelligent mother may well appreciate and find of value, even when not prepared to cross question the family attendant, as she might desire. The student of medicine, just passing from the threshold of the colleges to the more arduous walk of his professional life will also find in the handy liltle volume what may help him to glide more easily into the responsible place of the trusted family adviser.

◆

URINE TESTING (*b*)

WE question the advisability of letting a nurse's duties extend to the examination of the urine. This seems to us no less distinctively the sphere of the medical man than is auscultation or percussion. On the other hand, it is probably well that nurses should have an intelligent knowledge of the more simple methods of urine-testing, that they may learn to appreciate the necessity for regularity and care in collecting such secretion. For such an end, the little *brochure* before us is as good as any we know. The directions are given simply, and, in most instances, with sufficient clearness. The authoress has prudently not attempted to cover too much ground.

◆

SHARP'S THERAPEUTICS. (*c*)

A BOOK from the pen of this illustrious and venerable heretic in matters professional is sure to be worth reading, and will doubtless be read, notwithstanding the introduction of two uncouth and unfamiliar words into the title thereof. It may be well to premise that by "organopathy" the author means the local action of drugs, while to the supposed contrary action of certain larger and smaller doses of each drug, he gives the name of "antipraxy."

Dr. Sharp is profoundly dissatisfied with the present condition of the science of therapeutics, indeed he would withhold the use of the word science altogether in reference to it. In an age of therapeutical scepticism, which curiously enough goes hand in hand with the introduction of quite an army of new remedies, he has not found any difficulty in compiling a veritable indictment from the works of the best known therapeutists past and present. Having demolished, theoretically at any rate, the pseudo-science which, according to the author, our ignorance and our apathy has allowed to grow up, Dr. Sharp, as all conscientious reformers ought to do, proceeds to fill the aching void left by its erasure by a new system which is based on certain general laws which the author has deduced and which he ventures to hope, will do for medicine, what Newton's discovery did for astronomy, and what Dalton's law of combination in fixed proportions, has done for chemistry. Assuming the contrary action of large and small doses of drugs to be established, he suggests that the larger doses may be prescribed "to act contrary to diseases opposite to those produced by these larger doses when they are taken in health, as when opium is given for sleeplessness or diarrhœa;" or, the smaller doses may be given for the opposite condition caused by them in health as when opium is given for apoplexy or ill-health.

It is difficult and perhaps unnecessary here, to enter into a discussion on a proposition which involves so fundamental a change in the lines of thought hitherto followed. We can only leave it to his readers to appreciate the value and weight of his arguments undeterred by the rather declamatory style of the author who evidently feels very keenly the necessity for a change. We cannot help thinking, however, that it is poor tactics in attempting the introduction of a new system to commence by abusing unmercifully the very men who, after all, would have to inaugurate the change. If we may believe Dr. Sharp, wisdom is to be found and found alone, in the mouths of babes and sucklings.

◆

OUR TEMPERAMENTS: THEIR STUDY AND THEIR TEACHING. (*a*)

THIS essay, which is designated "a popular outline," deals with a very interesting subject, and therefore cannot be an entirely uninteresting book. But though we can congratulate the author on the choice of a topic, we can scarcely compliment him upon his workmanship. The matter is thrown together rather than digested: and it is difficult to see what practical result is to come out of it. The author's acquaintance with his subject is too limited, and, for instance, in discussing the significance of a long neck he is evidently unaware of what Bichat pointed out long ago about the long neck affecting the blood current from the heart to the brain; and he seems too to be unacquainted with Clifford Allbutt's description of the "neurotic" temperament, as well as many other like matters which appear in the works of well-known authorities. The book represents the desultory work of a man who has made the subject rather a pastime than a serious laborious task. In a brief chapter on "The Choice of a Profession" his remarks are sound, "although parents soon become aware of their children's likings and aptitudes, they are not, I think, sufficiently impressed by the important truth that success and happiness in after life are dependent on these having sufficient scope; and they would surely weigh them more carefully before accepting places for their sons in which their natural gifts must at best be wasted." Had this book been provided with a full, well-arranged index it would have had value for reference as a collection of notes bearing on the subject. The publishers have done their work well; and the illustrations are well executed and interesting.

◆

At the Societies.

MEDICAL SOCIETY OF LONDON.

THE first Lettsomian lecture of this year's series was delivered on Monday evening last, by Dr. Langdon Down "On some of the Mental Affections of Childhood and Youth." The lecturer showed how cases of mental weakness in the young are divisible into three categories (1) congenital, (2) developmental, and (3) accidental. He alluded to the hereditary influences at work in the production of the various forms of mental and intellectual feebleness, and to the peculiar types of face and skull which characterised the products of such degenerated offspring. We propose to give an abstract of this valuable and interesting paper in our next issue,

Royal College of Surgeons in Ireland.—At a recent meeting of the Court of Examiners, the following was admitted a Fellow of the College:—

Joseph Byrne.

Society of Apothecaries.—The following gentlemen passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on Dec. 23rd:—

G. A. Heaton Barton, Leonard Arthur Bidwell, Alfred Percy Blenkinsop, Alberto Pedro de Carvalho, M.R.C.S., George Martin Fox, Edward Bernard Harris, Philip Henry Hensley, Thomas Phillips, William Arnison Slater, Albert Edward Vidler.

The following passed on Dec. 30th:—

Notices to Correspondents, Short Letters, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attenion to this rule.

Reading Cases.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

Local Reports and News.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

MEDICAL DEFENCE.

To the Editor of the Medical Press and Circular.

Sir,—Kindly permit me to inform your readers that the "Medical Defence Union," whose circulars are being sent to members of the profession, has no connection whatever with the Medical Defence Association, of which Dr. B. W. Richardson, F.R.S., is President.

I am, Sir, yours, &c.,
George Brown,
Hon Sec. Medical Defence Association.

7 King William Street, E.C.
Jan. 3rd, 1887.

PRACTICAL!

An American contemporary gives the following very suggestive advice:—"From personal experience we would recommend our medical friends against advising their patients' families to remain at the seashore or on the mountain top till October, as by so doing they run the risk of being detained in the dry, hot, dusty city during the months of July and August of the following year with labour cases, and thus lose their much-needed summer rest."

Agricola.—Yes, a medical man is required to attend every performance of the Paris Hippodrome that takes place at "Olympia." Mr. Towers Smith is the responsible surgeon in charge.

M.D. Lond.—It is understood that eight Members (or rather Fellows) of the Council of the College are for the application to Parliament for powers to grant a doctorate to London students, while seven are opposed to such an application being made or such a concession being granted, and this being so, the Home Secretary will scarcely condescend to take the matter up. Some of the advocates of the measure urge that the Queen should be approached through Sir W. Jenner, and asked to exert her prerogative in the case, and so render unnecessary an application to Parliament. But it is doubtful if she possesses *per se* such a power, or if she would exercise it.

Lex.—The rising barrister you refer to, and whose acceptance of a magistracy you deprecate, suffered an amputation of a portion of his tongue a year or so ago, which interferes with his elocutionary powers, and hence we believe his acceptance of the vacancy referred to. It is worth, £1,500 a year, which is not so bad in these days.

Student.—You are correctly informed. "Griffiths' Text-Book of Materia Medica and Pharmacy" has been out of print for some time; we hear, however, that a new edition is in the press "Brunton's Text-book of Pharmacology" is not out of print, but we understand a new edition will shortly be called for.

Mr. G. B.—We deem it better not to use the editorial columns of the journal for the appeal.

M. D. S.—This appointment was, we understand, filled up some days ago.

Dr. Milton.—The climate of the State referred to is warm and semi-tropical. The mean annual temperature is about 60 degrees, and the annual rainfall excessive, averaging 63 inches. We have no information as to its suitability for medical emigrants; it has, however, doubled its population during the past twenty years, and contains at the present time about 1,500,000 inhabitants.

F.R.C.S. (London) will find the information has been utilised on reference to another column.

Dr. Murphy (Sunderland)—Your letter on "The Ætiology of Placenta Prævia" came to hand as we were at press. It shall appear in our next.

Dr. P. (Scarborough).—There is a good deal of truth in the opinion that "one, indicates physical; two, mental weakness," especially in provincial towns. The view would, however, be too sweeping, and would frequently not apply in large cities and country districts having an extensive area.

◆

Meetings of the Societies.

THURSDAY, JANUARY 6TH.

Royal Institution of Great Britain.—At 3 p.m., Prof. Dewar, The Chemistry of Light and Photography (adapted to a juvenile auditory).

Harveian Society of London.—At 8.30 p.m., Dr. T. Morton, The Analogy between Croup and Asthma.—Dr. Goodhart, Cases of Peritonitis.—Dr. Blenkinsop, Some remarks on Cancer and its Treatment.

FRIDAY, JANUARY 7TH.

West London Medico-Chirurgical Society.—At 8 p.m., Dr. Blenkinsop, Phthisis and its Treatment.—Dr. Seymour Taylor, The Etiology of Phthisis, and its Treatment from a Hygienic Standpoint.—Mr. Bruce Clarke, The Operative Treatment of Intercurrent Disease in Phthisical Patients.—Mr. H. Percy Dunn, Card Specimens of Pulmonary Tuberculosis.—Dr. P. S. Abraham, Specimens of the Tubercle Bacillus and Microscopical Sections of Tubercular Organs in Man and the Lower Animals.—Messrs. Wright and Co., An Exhibition of Oro-nasal Inhalers, Sprays, and Instruments.

MONDAY, JANUARY 10TH.

Odontological Society of Great Britain.—At 8 p.m., Communications from Messrs. L. Matheson, C. D. Davis, W. St. George Elliott, A. S. Underwood, S. J. Hutchinson, Morton Smale, and Joseph Walker.—President's Valedictory Address.

Vacancies.

North London Hospital for Consumption.—Resident Medical Office required. Salary £[illegible]0 per annum. Applications, with testimonials, to the Secretary, 2[illegible]6 Tottenham Court Road, London, W., on or before Jan. 17.

Worcester County and City Lunatic Asylum.—A vacancy for a Third Assistant Medical Officer. Salary £100 per annum, with board, &c. Applications, with testimonials, to Dr. Cooke, at the Asylum. by Thursday, Jan. 6

Inverness Northern Infirmary.—House-Surgeon and Apothecary. Salary £50, with board, &c. Applications, with testimonials, to Kenneth Macdonald, Town Hall, Inverness, on or before Jan. 14.

Newcastle-on Tyne Dispensary.—Resident Medical Officer. Salary £ 50 per annum, with furnished house. Applications to the Hon. Secretary. Nelson Street, Newcastle on.Tyne, on or before Jan. 12.

Appointments.

Dunlop, G. H. M., M.D., M.R.C.P.E., Extra Physician to the Royal Edinburgh Hospital for Sick Children.

Dutt, A. [illegible], B.A Cantab., L.S.A., Resident Medical Officer to the Morpeth Dispensary.

Douty, J. H., M.R.C.S., Medical Superintendent of the Berks County Asylum.

Hudson, L., M.R.C.S., L.R.C.P.Lond., Pathologist and Curator of the Museum to the Middlesex Hospital.

Hurlbutt. S., M.R.C.S., L.R.C.P.Lond., Assistant Medical Superintendent to the Fulham Union Infirmary, Hammersmith.

Morgan, W. P., B.A., M.B., B.Ch. Univ. Dub., Medical Officer and Public Vaccinator to the Seaford District of the Eastbourne Union.

Pearson R., M.R.C.S., L.R.C.P.Lond., Junior Assistant House-Surgeon to the Hull Royal Infirmary.

Births.

Hamilton.—On Dec. 30th, at Enniskerry, the wife of James Hamilton, M.B., of a daughter.

Hanley.—On Dec 31st, at 3 Upper Phillimore Gardens, Kensington, the wife of Ed. Hanley, M.D., of a son.

Hudson.—On Dec. 23rd, at Bridge House, Dingle, the wife of Robert Hudson, Esq., M.D., of a son.

Martin.—On Dec. 29th, at 76 Brunswick Street, Sheffield, the wife of Dr J. W. Martin, of a son.

Rice.—On Dec. 25th, at Sutton, Surrey, the wife of Geo. Rice, M.B. of a son.

Marriages.

Murray—Matheson.—On Dec. 29th, at Edinburgh, Donald Roderick Murray, M.B., C.M., Admiralty Surgeon and Agent, Leith, to Johanna (Bunty), daughter of the late Robert Matheson, Esq., of H.M. Board of Works, Edinburgh.

Fox—Danger.—On Dec. 30th, at the Parish Church, Brislington, near Bristol, Bonville Bradley Fox, M.A., M.D., of Brislington House to Annie, youngest daughter of the late Thomas Danger, Esq., of Gotley Lodge, Brislington.

Deaths.

Bell.—On Dec. 14th, at his residence, Merlin, Eastbourne, William Bell, M.D., L.R.C.S.I., in his 83rd year.

Bompas.—On Nov. 3rd, at Busselton, Western Australia, C. Smith Bompas, M.R.C.S., formerly of Bristol, aged 68.

D'Arcy.—On Dec. 29th, at Northampton, of acute bronchitis, O'Connor D'Arcy, Army Medical Department (retired).

Dickinson.—On Dec. 27th, at 162 Bedford Street, Liverpool, Annie, the beloved wife of Edward H. Dickinson, M.A.Oxon, M.D.

Greaves.—On Dec. 10th, at Burton-on-Trent, George Greaves, L.S.A., in his 82nd year.

Grover.—On Christmas Day, suddenly, at St. Anne's, Lewes, John Pollington Grover, M.R.C.P.Ed., M.R.C.S., L.S.A., aged 28.

Nankivell.—On Dec 24th, at Ashley Lodge, Torquay, Chas. Benjamin Nankivell, M.D., aged 81.

O'Callaghan.—On Dec. 24th, at his father's residence, Sea View Lodge, Ballybunion, Surgeon John O'Callaghan, R.N., late H.M.S. *Impregnable*, aged 33.

Taylor.—On Dec. 17th, at 5 Ashley Road, Bristol, Frank Taylor, M.R.C.S., L.S.A., late of Redcliff, Bristol, aged 30

Traill.—On Dec. 10th, at North Street, St. Andrew's, Fife, William Traill, M.D., of Woodwick, Orkney, aged 68.

THE

Lettsomian Lectures

ON

SOME OF THE MENTAL AFFECTIONS OF CHILDHOOD AND YOUTH. (a)

By J. LANGDON DOWN, M.D. Lond., F.R.C.P.,
Senior Physician to the London Hospital.

ABSTRACT OF LECTURE I.

History of the Subject.—In dealing first with the history of his subject, the lecturer said that the earliest attempts at the education of idiots were isolated efforts under the direction of M. Séguin, at the Bicêtre; but, in 1842, attention was more particularly directed to the subject by the establishment of a school on the Abendberg, in Switzerland, which was opened by Dr. Guggenbühl. About the same time, M. Saegert, at Berlin, who had been engaged in the instruction of deaf mutes, extended his efforts for the benefit of a class, whose mutism was not the outcome of deafness. In 1846, a general movement took place for ameliorating this afflicted class. Germany took the lead by the establishment of a school at Leipzig. Discussions in the periodical press were initiated by Mrs. Plumbe, of London, whose personal interest in the matter forced the subject on the attention of Dr. Conolly and Dr. Andrew Reid. Synchronously, public attention was given to the subject in the United States of America, where, while politicians were delaying action in the matter, the private enterprise of the late Dr. Wilbur brought it to a practical issue. England meanwhile commenced the work by the establishment of a small school at Bath. It was not, however, till 1847 that the great effort was made which resulted in starting a small institution at Highgate in 1848, and subsequently another at Colchester. These grew into the large institution at Earlswood. In recent years other institutions have been created both in England, Ireland, Scotland, the United States, and on the continent of Europe.

Nomenclature.—Passing to the nomenclature of his subject, the lecturer commented on the loose way in which the terms imbecile and idiot were used. He thought that the term "idiot" might be advantageously replaced by that of feeble-minded, idiocy being, in fact, mental feebleness depending on malnutrition or disease of the nervous centres taking place anterior to birth or during the developmental years of childhood and youth. The term "imbecile" should be applied to the cases of dementia in which there was a gradual deterioration in physical, mental, and moral condition.

Etiological Classification.—A large number of feeble-minded children were capable of being referred to one or other of two great groups, (1) the congenital, and (2) the accidental. But there were many instances which it was impossible to include in either of these categories, cases where the early months of babyhood were perfectly uneventful, and intelligence had dawned in the accustomed way, but where, during first dentition, a change came over the aspect of the child; in others, the crisis at first dentition was not so marked; speech was only deferred, but, at the second dentition, crises occurred in which the intelligence became altered; there were night terrors, and not infrequently loss of speech, or the break-down was reserved for the time of puberty.

These cases, the lecturer said, have usually characteristic crania; they are dolichocephalic, and are prow-shaped anteriorly, the line corresponding to the medio-frontal suture being a prominent ridge. There is reason to believe that in these cases there has been an arrest of the synostosis of the medio-frontal suture which should have taken place during intra-uterine life, so that the lateral pressure on the separated frontal bones determines, when the deferred ossification takes place, a prominence where there should have been a plane or slightly concave surface between the frontal eminences. In the great bulk of these cases, well marked evidence can be obtained of some disturbing cause towards the later months of pregnancy, which has led to this condition; and although the deferred synostosis and its consequent deformity is of no consequence, it is reasonable to believe that the same cause which arrested the bony union has also arrested the development of the cerebral centres, and rendered them more unstable. Certain it is that children with such a conformation are almost sure to break down at one or other of the developmental epochs. Their nervous system would appear to be equal to the requirements of growth but not of development. They form a class of cases which I have suggested should be called the "developmental," as contra-distinguished from the congenital on the one hand, and the accidental on the other. They are a very important class because, forewarned, catastrophes may be avoided. They are the cases which break down by over-excitement in babyhood, and by "over-pressure" in schools at second dentition and puberty.......A large number of boys and girls come under my notice who are not feeble-minded, who have in a high degree the prow-shaped forehead, and who have their nervous system in such an unstable equilibrium, that the least intellectual pressure at developmental epochs is attended by disastrous results. They are brought to me on account of severe frontal headache, or of wayward petulance, or incapacity for sustained mental exertion.

After quoting with approval Dr. West's statement that he had "never known a child stammer before the commencement of the second dentition," Dr. Down proceeded to describe the group of cases to which he applied the term "accidental," children born, or ready to be born, with all the potentiality of intelligence, but whose brains became damaged by traumatic lesions, by medications, or by inflammatory disease. The great characteristic of the class was the absence of any of the physical aspects of feeble-mindedness; bright in their expression, often active in their movements, agile to a degree, mobile in their temperament, fearless as to danger, persevering in mischief, petulant to have their own way, but with a language of gesture only. They were the cases in which mothers entertained the strongest hope. But there was need of great caution in prognosis, as they were most disappointing. So interesting were the children in appearance, that it was difficult to realise that they would not be perfectly responsive to training, and that speech would not be speedily gained. They had well-formed heads, finely-textured skins, well-chiselled mouths, sparkling eyes, features when in repose leading one to augur only brightness and intelligence. There was no outward sign of mental vacuity, for there had been nothing during the period of intra-uterine life to arrest the evolutionary stages, and stamp its impression the bodily or facial formation. The cause of the mental deficiency had been something occurring during post-uterine life—some catastrophe not inherent in the child—not a hereditary taint to mar the beauty of his visage or the grace of his cranial contour; yet there was something more potent for evil than in the case of many a malformed face and many a distorted skull. Though much might be done by training to divert the energy into better channals, the improvment would be smaller than might be obtained from apparently less promising children, because more development could be obtained from an ill-developed than from a damaged brain. The remaining class—the congenital—contained by far the largest number of subjects. Less interesting in appearance but more amenable to training, the origin of their malady dated from earlier in intra-uterine life, in many cases the proclivity resided in the germ-cell or sperm-cell, as the result of gradual degeneration, and the children bore in their bodily formation marks of physical change. They for the most part had a tendency to fall under one or other of the ethnic groups above mentioned. In these cases, said the lecturer, the cranium is usually smaller than normal, dolichocephalic in many, but brachycephalic in the Mongolian type. Occasionally the head is scaphocephalic, the line of the sagittal suture giving a keel-like feature to what resembles an inverted boat. A very common character is a rapid shelving from the vertex posteriorly, corresponding to what is so frequently to be noticed, an arrest of development of the occipital lobe of the cerebrum. Not infrequently the cranium is extremely small, reverting to the Aztec type. These examples of extreme micro-cephalism have been attributed by Virchow to premature synostosis of the cranial sutures. I have found, however, that in some of the most marked members of the micro-cephalic group the sutures are well marked, and there is every indication that the cranium had adapted itself to the cerebrum rather than that the cerebral mass had been dominated by the cranium. They are cases in which the brain and bony covering are both in miniature, the arrest having had an early intra-uterine date. It would be a grave error to imagine that there is an inverse relation between the size of the cranium and the intellectual capabilities of its possessor. . . . Macrocephalic crania are not infrequently met with, some being due to hydrocephalus, and others to an increase of the neuroglia of the cerebral mass. I have had patients under my care whose brains were within an ounce of the weight of that of Cuvier, who, nevertheless, were slow in their movements, and slower in thought, and were perfect contrasts in intellectual sluggishness to the volatile micro-cephalic Aztecs with brains only one-fourth the weight. An inspection in these cases revealed the fact that the cineritious portion was pale and that the increased weight was due to the increase of the white substance, and especially of its connective-tissue elements. Another deformation met with in congenital feeble-mindedness is a marked asymmetry of the two sides of the cranium. There is also in many an increase of the facial development as compared with the cranial. The ears are implanted farther back relatively than in normal heads. The eyes have their canthi too closely approximated in the dolichocephalic cases and too widely separated in the brachycephalic. The palpebral fissures are often narrow and obliquely placed, and the forehead is, not infrequently, corrugated in consequence of the employment of the occipito-frontalis muscle to raise the lid. At the inner canthi the integument often forms semilunar folds, as if the skin were too scanty, which I have proposed to call epicanthic folds. These are met with in people who are not feeble-minded, but they are more frequent in the latter, and are, I believe, signs of degeneracy.

(a) Delivered before the Medical Society of London, January 3rd, 1887.

Dr. Down considered the deformations of the mouth as very important in the diagnosis of congenital idiocy. His views had been very generally adopted, and were confirmed by many members of the Odontological Society of London when the subject was brought before them. But they had met with opposition in two different quarters, and for different reasons. Dr. Kingsley, of New York, had been led to conclude, on general grounds, that the examination of a series of idiots would probably show that they had capacious jaws, and teeth which were not crowded; this reasoning appeared to be confirmed by an examination of the inmates of an asylum for idiots on Rundall's Island; in about two hundred children not a single case of pronounced V-shaped dental arch was found. Dr. T. Claye Shaw had tried to show that there were many idiots with well-formed mouths and palates. With this I agree if he includes accidental and developmental cases. My contention is that they are typical of the congenital class. Dr. de Bourneville, of Paris, has carried on investigations on the same subject in France, and in a memoir has generally confirmed my views. Dr. Ireland, in his treatise on "Idiocy and Imbecility," says, "Dr. T. Clay Shawe took the trouble to write a paper to prove that a highly arched palate is not a sign of the existence of idiocy and imbecility; that a palatal investigation cannot afford a clue to the mental faculties. Dr. T. Claye Shaw's paper illustrates the confusion of mind one must fall into who studies the physical aspects of idiocy, while he persists in regarding it as a class incapable of further subdivision."

Common sensation is generally much less acute than in ordinary persons. Pain is borne with wonderful callousness. Special sensation is also obtuse. Hearing is generally less acute, and this is often an important element in cases of delayed speech. We all know that absence of speech is often the outcome of complete deafness, but it is not sufficiently recognised that a very slight congenital defect of hearing is sufficient to cause deferred and defective speech. Lesions of sight are very frequent. Congenital cataract is very commonly associated with congenital feeble-mindedness. Several cases have also come under my notice of blindness, the result of arrested development of the globe.

Strabismus is very common, and nystagmus, though less common, is not infrequent. Myopia, but especially hypermetropia, is a frequent accompaniment of congenital mental lesions. Colour-blindness is occasionally met with, but it is difficult to say in how many cases it is from a want of mental power. The sense of smell is ill-developed in a great many, and that of taste keeps company therewith. The most nauseous medicines are taken without question, and in fact with many, its administration is regarded as a mark of attention and appreciated accordingly.

The muscular system is weak. Not only are physical efforts feeble, there is no power of sustained endurance. Co-ordination is defective and finely adjusted movements are exceptional. There is a great tendency to automatism and rhythmical actions. Salaams, horizontal swayings and rotations of the head and body are often met with. The lack of muscular power makes itself painfully manifest in a number of instances by the postponement of walking or even of standing. . . . . . In the large number of notes which I possess of congenitally feeble-minded children, walking delayed to the third or fourth year is a very common occurrence. Imperfect prehension with the upper extremities is also a frequent characteristic, and often the vertical position is rendered impossible by virtue of muscular weakness long after children of a similar age are running about. Delayed speech is universal, permanent absence less common.

Clinical Paper

ON

SOME CASES INVOLVING LAPAROTOMY.(a)

By A. RABAGLIATI, M.A., M.D.,
Senior Surgeon to the Bradford Infirmary, and to the Children's Hospital.

MR. PRESIDENT AND GENTLEMEN,—Under the title of "Cases Involving Laparotomy," I wish to describe three recent cases which have been in the Infirmary. (Perhaps a word or two may be allowable as to the meaning of the term λαπαρὸς, adjective, and λαάπ,ᾶ, or η, which is the root of the word. The adjective means *slack*, or *loose*. The phrase λαπαρὰ γενέσθαι is used by Aristotle of *having the bowels open*, just as we speak now of their being loose. Perhaps you will think it hypercritical, but when we cut the soft parts for abdominal tumour—I think Mr. Lawson Tait suggested the term laparotomy originally—they are in general anything but slack or loose, but are almost always, on the contrary, tense and firm and stretched. Then as to λαπάρᾶ, the noun, this is used of the soft parts of the body between the ribs and crest of ilium, hence *laparotomy* may be applicable to one of my cases, that in which the kidney was removed by the flank, but is hardly in strictness applicable to ordinary abdominal section in the middle line, in front. I understand that Mr. Tait suggested the word laparotomy to mean simply section of the soft parts in abdominal operations; but would not the term *malakotomy*, or *malacotomy* (μαλακὸς = mollis = soft, opposed to σκληρὸς = durus = hard), have been a more approximate name? I suppose operations like nephrectomy and others which involve division of the tissues in the flank, will have to be performed in the future from time to time. In this case we shall require a term to distinguish sections of the flank from sections of the abdominal parietes anteriorly, as in operations for the removal of ovarian tumours. I suggest, therefore, that in future the term laparotomy, at present used generally, should be restricted to cases in which the abdominal parietes are divided from the flank, since λαπάρα means the flank, while *malakotomy*, or *malacotomy*, should be used in those cases in which the abdominal parietes are divided from the front. In the term *osteo-malacia*, which is classic, we have the root of the proposed new word.)

My three cases are: 1st. A very instructive case of cancer of the abdomen, beginning apparently in the omentum; 2nd. A case of parovarian tumour; and 3rd. a case involving left nephrectomy, the first I have performed, and, I almost think, the first operation of the kind done in Bradford. The whole three cases are very interesting and important. The first, having been named cancer of the abdomen, may seem a very easy case to diagnose, but it was, in fact, anything but that. Mr. Kempe has condensed Mr. Carter's notes (for the woman came in as a medical case) and thus completed the history. I may add I am indebted to Mr. Kempe for the notes of the other two cases also.

H. W., married woman, æt. 52, admitted into the medical wards under the care of Dr. Alexander, 27th October, 1886 She was transferred to my care on 12th November. The family history was good. Personally she had suffered from dyspepsia for four years. No previous illness whatever. Married, seven children alive. No miscarriage. Menstruation regular up to menopause, three years ago. For last three months has suffered from flatulence and swelling after food, but the swelling always went down in a few days. One month ago began to vomit after food. Abdomen has gradually increased in size. Up to three weeks ago worked as a weaver, since then has done household duties. Is a pale, delicate-looking woman, who has lost most of her teeth. Temperature is slightly elevated in the evening. Has pain across loins, and tightness across abdomen, but no actual pain there. Abdomen distended; distension principally confined to lower two-thirds, swelling slightly more prominent on the left side; feeling of resistance in left ileo-lumbar region. Percussion note tympanitic. Deep percussion on left side dull. A fluid wave can be felt propagated from one side to the other. No increase of hepatic or splenic dulness. Heart and lungs natural. Urine sp. gr. 1030, with heavy deposit of pink lithates, no albumen, no sugar. *Per Vaginam.*—Uterus low down in a short vagina; partial prolapse of anterior vaginal wall. No increase in size of uterus, which is freely movable; in Douglas's pouch no bulging.

November 7th.—At the request of Mr. Carter, I explored abdomen with Dieulafoy's aspirator. On first insertion no fluid came, but on second puncture in left ileo-lumbar region ℥xv of blood-stained fluid was withdrawn; sp. gr. 1015; solid with albumen. Up to a few days before this time the provisional diagnosis had been *flatulent distension of abdomen; dyspepsia.* It now became *left ovarian tumour*, and I suggested from the appearance of the fluid that the tumour might be malignant, but it seemed to me nearly certain that it was ovarian. The sequel, however, showed that this was a mistake, although the percussion and finding of the fluid where I expected to do so, seemed to confirm the diagnosis.

On 15th November the woman was a good deal worse, there was more fever, and the abdomen had considerably increased in size. A consultation was therefore called at which Messrs. R. H. and H. Meade appeared. It was thought inadvisable to perform laparotomy (malacotomy) then, although the dulness in the left flank was again made out, and, in addition, a plain ascitic wave was felt. Aspiration was recommended, and if the patient improved under it, it was thought abdominal section might be performed later. The aspirator was therefore again used. It was plunged in three times deeply, but each time it failed to draw fluid, the fourth time it drew forty-eight ounces of blood-stained fluid similar to what had been got before. After operation, tension was considerably lessened, but measurement of abdomen not so. In left ileo-lumbar region, nodulation of tumour could be distinctly felt, and the ascitic wave was even more perceptible than before. Sp. gr. of fluid, 1020; albumen, half. To have ice, soda water and brandy; pil. opii, gr. i, t. d. s.

17th Nov.—Patient seemed to have improved, with less fever and better aspect, so at 9 a.m. laparotomy (malacotomy) was performed under ether, with carbolic spray. When abdomen opened in middle line, a rush of red fluid occurred from the peritoneal cavity, and soon particles of jelly-like matter appeared. On passing hand into abdomen, a mass of this jelly-like material was found to fill the cavity, and this it was evidently which had plugged the end of the aspirator so that it was necessary to insert it on the first occasion twice, and on the second occasion of aspirating, four times, before fluid was drawn. The mass of colloid cancer being everywhere adherent, the wound was closed, after eighty-nine ounces of fluid had been withdrawn. The operation did not seem to have any deleterious influence on the patient, even appearing, indeed, a little to relieve her by removing the ascitic fluid; but she died on the 21st November. No post-mortem examination was allowed.

The only remarks to be made about this case are: 1st. The peculiarity of the position of the dulness in the left flank, making me feel pretty certain that we had to do with left ovarian tumour. It may, of course, have been the case that some temporary cause made the abdomen duller there than elsewhere on the first examination, and that the tyranny of a preconception misled me afterwards. 2nd. The appearance of the bloody fluid (which evidently was ascitic, though I thought it came from a cancerous ovary) and the rapid downward progress of the case made me expect to find cancer of the ovary, although

---

(a) Read before the Bradford Medico-Chirurgical Society, December, 1886.

I must confess I did not expect to find colloid cancer of the omentum. I once operated after correctly diagnosing an ovarian tumour, and removed it. It was filled with fluid very like what was found in this case. A few months later I was asked again to see the lady, and I diagnosed incipient cancer of cervix uteri, of which disease she died in a few more weeks. 3rd. Probably a more thorough consideration of the question why it was necessary to insert the aspirator twice, and four times in place of once on each occasion should have enabled me to diagnose abdominal cancer, not confined to an ovary; but it is easy to be wise after the event. And in this case as no post-mortem examination was allowed, there would still have been some doubt as to the exact nature of the case, whereas now there is none. Lastly, this interesting case shows that some apparently dyspeptic cases, especially in patients beyond the meridian of life, should make us very cautious as to diagnosis and prognosis, lest, like this one, they may possibly turn out to be cancerous.

The second case, one of right parovarian tumour, has the following history. W. J. Timms, æt. 33, housewife, admitted 3rd November, 1886, was confined three months ago, and has never been well since. Has had eight children. Has been swollen in abdomen for four years. Two months before her confinement, her feet were swollen, and have remained so ever since. After her confinement, her doctor told her she had a tumour. No menstruation since confinement. None of her family have had tumours of any kind.

State on Admission.—Skin of abdomen much wrinkled. Abdomen generally enlarged and "wabbly," yielding in every direction without offering any particular resistance. Percussion tympanitic in left flank, but right flank dull as far as umbilicus. There seems to be a great quantity of superfluous skin over abdominal wall. *Per Vaginam.*—Cervix uteri rather hard. Sound passes the normal two and a half inches. Girth at umbilicus easy thirty-nine and a half inches; keeping the tape on the same line at the back, but passing it in front midway between pubis and umbilicus, the measurement was forty inches. Urine 1020, acid, pale; no albumen.

November 13th.—Measures forty-one inches at umbilicus.

14th.—Paracentesis by Dieulafoy's aspirator, one hundred and eighty-eight ounces of light brownish-yellow fluid withdrawn. After paracentesis, measurement thirty-six inches. Percussion note in right flank now clear. (Patient states that when her last child but one was born four years ago, the medical attendant found nothing in the way of tumour.) The fluid withdrawn had sp. gr. 1010, and showed a cloud of albumen, about one-twelfth.

27th.—Measurement at umbilicus, thirty-five and a quarter inches. Discharged.

In the last thirteen days the abdomen had not appreciably enlarged. After tapping, no cyst or tumour of any kind could be felt, no irregularities or nodulations. There was no pain, only a feeling of discomfort in getting about, and some swelling of the feet till she was put to bed, when it disappeared. The history of the case shows that we had a unilocular cyst to deal with. No doubt this is the kind of case which used formerly to be confounded with multilocular ovarian cystoma, and the history of which seemed to justify the advice then given to tap such cases in the hope of curing them. Occasionally, we were told, tapping cured such tumours, therefore tap in the hope of obtaining such a result, it was said. I suppose we may now say, ordinary multilocular ovarian tumour is never cured by tapping, and where such tumours have been thought to be cured by this means, it has been so considered because they have been confounded with cases like the present, namely, with cases of parovarian cyst. There are differences in the character of the fluids from ovarian tumour and from parovarian cyst, which help diagnosis. Instead of the thick gelatinous fluid generally (though not, I must say, always) got from ovarian tumours, with a sp. gr. of 1010 to 1025, and a large quantity of albumen, we have a watery opalescent fluid of sp. gr. 1008 or 1010, with little or no albumen. In my case the fluid was not so clear-coloured as usual, being of a light brownish yellow colour, perhaps from the admixture of blood some long time ago. But, if so, there could not have been much blood, or we should have found more albumen. The watery coloured fluid is the usual description, but I fancy the deeper colour may be not unusual, for Dr. J. Matthews Duncan also describes a case where the fluid was deeper coloured than usual. My own experience is not large in this sort of cyst.

What becomes of the tumour after tapping? In answer to this question, Dr. Duncan mentions a case of a rare dissection recorded by Professor Gairdner. His patient had a large abdominal swelling produced by a great cyst, which suddenly and unexpectedly burst and the swelling disappeared. Sixteen months thereafter she died of Bright's disease. Dissection revealed a small parovarian cyst, which was empty, and if distended might have equalled in size a fœtal head. The place of rupture was made out by Dr. Coats, and was shown me (says Dr. Duncan) by Professor Gairdner. Though the rupture was healed, the cyst had not shrunk and had not refilled.

What is parovarian cyst? Dr. Duncan says: "The parovarium in the female corresponds with the epididymis in the male; and it consists of a series of tubules running from the hilus of the ovary along its mesentery towards the neighbouring tube. In this disease one of these tubules is dropsical, distended with a thin fluid. It is said that the affected tubule is generally one of those most distant from the uterus. In most cases, but not invariably, one tubule only is affected, and the cyst is truly, anatomically unilocular. It has been observed to be bilocular in rare examples, or even trilocular, but in the disease we are now describing the cyst is never multilocular, never proliferating."

My third case is one of left nephrectomy for pyonephrosis. Eliza H., æt. 31, married, had been treated as home-patient for four months for an abscess in the left loin. She had been confined 1 year 9 months ago, and had never been well after, menstruation never returning. A month or two after confinement had pain in the abdomen which began to swell. Four months ago swelling became much worse, bulging towards left loin, where an abscess formed which was aspirated and subsequently burst. Has had two children and two miscarriages. Husband died of phthisis. No phthisis on her own side so far as known. Is a pale woman, thin, fair; finger-tips not clubbed; nails slightly curved; no cough. Feels as if she wanted to micturate frequently, but passes only a small quantity at a time. No swelling of feet or of eyes in morning. Urine acid, 1015, cloudy, albumen.

November 22nd, 1886.—Two days after admission. On left side, midway between last rib and iliac crest is a sinus, skin around it red and excavated. Probe passes readily in all directions, but furthest towards spine (about 4½ inches). No bare bone felt when passed towards rib. No splenic enlargement. No marked bulging of flank on left side of abdomen. Palpation negative; no increase of hepatic dulness; no tenderness of spine on percussion, although spines of 9, 10, and 11th dorsal vertebræ rather prominent. Chest: Left apex does not expand so well as right. No râles at apices. Slight râles at both bases posteriorly. Wet boracic dressing applied twice daily.

25th.—No pain over either sacro-iliac articulation. More discharge this morning. Temperature last night 103° F. Perspires a good deal at night.

28th.—Hacking cough; pain in chest; alæ nasi dilating; facial respiration; impaired resonance in chest; bronchial respiration and fine râles heard at left posterior base; probably tubercular. Turpentine to left posterior base.

30th.—Omit fomentations. Brandy ℥v and milk. Same date 12.35 p.m., under ether, the sinus was enlarged transversely and *nephrectomy* performed. Finger passed into wound readily felt kidney. *Fascia lumborum* was perforated by the abscess. The external oblique as exposed was pale and flabby. Kidney had but little fat surrounding it, and though very soft was stripped from the surrounding tissues. The hilus exposed, pedicle ligatured by stout silk and removed. There was a little hæmorrhage from the pedicle, it being difficult to get ligature to hold, owing to the softness of the parts. An aneurism needle was, therefore, used to pass the ligature deeply, and after it had been divided at the loop the pedicle was tied in two parts. Drainage tube inserted; edges of wound stitched with catgut; carbolic oil dressing applied with oakum. On section the kidney was found to be full of tubercular abscesses containing creamy pus. No tubules seen on surface.

9 p.m.—Quite rallied from operation; feels weak; no hæmorrhage.

December 2nd.—Free discharge from wound. Pain in left leg, left foot swollen. Her water came away from her during the night.

3rd.—Left foot and leg more swollen, veins distended, tender along inner side of knee and thigh; no redness, no rigor or sweating. ℞ M. quininæ gr. ij, ad ℥j. t.d. s.

4th.—Left leg more painful. Urine sp. gr. 1010, acid, cloud of albumen.

5th.—Better; leg less painful.

7th.—Had good night, and feels much better; ate her chicken yesterday and enjoyed it. Passes plenty of urine (about ℥iv at a time). Wound granulating healthily; ligature has not yet separated; left leg no pain, swelling much less. Says she feels better than before operation.

13th.—Ligature not yet come away; swelling right foot; small abscess just anterior to right great trochanter opened.

14th.—Ligature came away.

The patient is making a good recovery.

NOTES FROM THE HISTORY OF MEDICINE AND OF MEDICAL OPINION FROM THE EARLIEST TIMES.

By Surgeon-General C. A. GORDON, M.D., C.B.,
Hon. Physician to H.M. the Queen.

Continued from p. 568, Vol. xlii)

In the twelfth century Benjamin of Tudela,(*a*) a Jewish rabbi, gave an account of what cities, up to that date, the Jews had any settlement in. He mentioned a great many physicians among them, some of whom extended their practice also to Christians. Charlemagne had two such in his service, namely Farragatus, Butiahyliha Bengesta, who, by his order, composed the book called *Taucin*, or the Tables of Health, that is, a sanitary code; time, the ninth century. Before the close of the tenth century the Jews, being masters of the Arabic language, were the chief physicians in Europe, their system, chiefly that of the Arabians. They were received by several Popes, and by the Mahomedans; so much so, that after the irruption of the Moors into Spain, A.D. 714, the Moors assigned to them Cordova and Grenada for their habitation. They had indeed a sort of University very early, *i.e.*, about A.D. 200, at Sora, in Asia. In the beginning of Mahomedanism, namely, in the seventh century, several of them were employed by the Caliphs, some of them at least, there is reason to believe, following ordinary business while they also practised physic.

In the latter portion of the twelfth century a Benedictine monk named Ægidus, physician to Philip Augustus, wrote a treatise in hexameter verse on the properties of drugs, a treatise which is stated to have been adopted for some time afterwards as a text-book in the schools. [It is not so long ago that a treatise in verse on medical subjects was written by the clever author of "The Fallacies of the Faculty." And every now and then some popular and ephemeral theory is discussed in a similar manner in the periodicals of the present day, medical and non-medical.]

It was about this period also, including the early part of the thirteenth century, that Albertus Magnus began the studies in medicine with which his name is associated. He devoted much of his time to the search after the philosopher's stone and the "elixir vitæ," those *ignes fatui* which, as we shall see by-and-bye, deluded the wisest men at a much later and more "enlightened" age. Magnus, too, was not a medical man, but a monk, yet undoubtedly his researches in chemistry proved of very great service to medicine and to therapeutics.

In the thirteenth century chemistry as a distinct branch of study took its rise in Europe, and to Roger Bacon the honour is due of having originated that study. With him, as with Albertus Magnus, the pursuit of the philosopher's stone was enthusiastically prosecuted, as indeed it had already been in China. But as even happens in more recent times, so in the thirteenth century, Bacon concealed a great deal of useful information under "that jargon of language which was so fashionable in those times." Another discovery, namely, that of gunpowder, assigned to Bacon, leads us to believe that as with respect to the philosopher's stone, so in regard to the latter, he must have had access to the literature of the Far East, for not only was the explosive alluded to known in China from very ancient times, but it appears to have been so also by the Aryans, very soon after, if indeed not previous to their descent into India. Bacon also was not of the medical profession, but a friar, whose "study," real or apocryphal, may still be seen at Oxford. Curious and suggestive it is that, although the first result to himself of his investigations was a money endowment to enable him to purchase the instruments and other appliances necessary for the pursuit of his experiments, the second result was persecution, the latter chiefly by his own fraternity.

Among his works which more particularly concern our present purpose may be enumerated those entitled "De Erroribus Medicorum." [It is obvious that the doctrine enunciated in recent times that only "experts" in such matters were capable of discussing them was not then recognised]; "De Prolongatione Vitæ," "Antidotarium Vitæ Humanæ," &c. He extolled the virtues of vipers' flesh in phthisical cases; and that remedy continued in favour until a comparatively recent date, as indeed it had been in China, in Greece, and elsewhere, centuries prior to the time of Roger Bacon. At the present day doubtless a palatable substitute for vipers' flesh is found in that of another reptile, namely, the turtle. Bacon gave to medicine a new impulse by introducing the study of the "exact" sciences and experiments as means of obtaining knowledge. And yet, notwithstanding all his "exact knowledge" and his experiments, history relates that Bacon "believed in the possibility of an universal medicine, the basis of which belief was astrology" (*id.*, p. 187). [And at the present day, philosophers, experimenters, and men of "exact" science believe in "possibilities" the bases of which are no more solid than were those of Bacon's conviction as here expressed.] He advocated the strict examination of the opinions of his predecessors, and so the contradictory tenets of Aristotle and Averrhoes, of Galen and Avicenna, each of whom was judged to be infallible, came to be, if not the chief, at least a great part of medical education. A system of reasoning on abstract questions without reference to facts was thus sanctioned. [Indicating how readily men of "exact" science may themselves be led away from what is definite and precise to what is speculative, abstruse, and abstract.]

Contemporary with Bacon was Petrus de Apono. He

(*a*) Tudela, a city of Navarre, in Spain.

was distinguished for his skill in chemistry as well as for his knowledge of medicine. The principal characteristic of his life, which has come down to our time, is that he devoted a special work to the task, laborious even then, to reconcile differences of opinion which existed between professors of medicine, from which circumstance he obtained the title of "Conciliator." He also wrote a treatise on "Poisons and their Antidotes," another on "Astrology in Relation to Diseases." In the manner of his death his name is recorded in the long list of victims of the "Holy" Inquisition, A.D. 1319.

At the same period also lived Arnoldus de Villa Nova, or Arnaud, of Villeneuve, in France. He studied in Spain the language of the Arabians and their method of medical treatment, in which he himself was so successful, that a medical sect, under the name of *Arnoldistæ*, was so called after him. Besides various distilled medicinal "waters," including *aqua euphrasiæ*, &c., he mentioned the distillation of ardent spirits as a recent discovery, and under the conviction that it was the long sought for panacea for ensuring longevity, gave to those spirits the name of *aqua vitæ*. He also wrote a treatise on the "Government of the Health." He founded his practice of medicine on astrology. Notwithstanding that, in prescribing he turned himself towards the planet Jupiter as it crossed the meridian by way of invocation, he proposed an important question which, until quite recently, interested physicians, namely, the policy of depletion by bleeding at the beginning of every acute disease.

Brunus, an Italian surgeon of the same period, professed to publish an account of operations from his own personal experience. His description of lithotomy, however, is stated to coincide with that given by the Arabian surgeons, more especially by Albucasis. Brunus recommended the opening of the sinuses in cases of fistula in ano. [An operation still practised.]

After Brunus the practice of medicine was followed by Theodoric, Bishop of Cervia. He published a work on surgery, in which he adopted and appropriated the recommendation by Brunus, "to break a badly set bone a second time," or, in cases of longer standing, "to use the knife" for that purpose. He mentioned the propagation of elephantiasis by means of coitus with an infected person. He noticed the manner of preparing unguents, and gives particulars in regard to the induction of salivation by their means when used externally. It is asserted, however, that these mercurial applications were borrowed from the Arabians. (Hamilton, vol. i, p. 360.)

William, of Salicetum, also in the thirteenth century, based his own practice upon "long and careful (clinical) observation." He assumed it was an axiom that medical knowledge was only to be acquired from practical experience. He describes the operation of lithotomy as performed in females. He mentioned that he had never seen a case of hydrocephalus cured by an operation. He was the first to treat of the "crusta lactea;" and to recommend surgical operation in cases of sarcocele. He described the treatment of wounds, including those which penetrated the thorax. He pointed out the difference in function of the nerves which originate in the cerebrum, and of those which proceed from the cerebellum and spinal cord; and the coincidence between his opinion on the subject, and that expressed by Willis several centuries afterwards, is noticed by his biographer. (Hamilton, vol. i., p. 364.)

In the same century (namely, the thirteenth) the study of human anatomy took a new departure under Mondinus, of Bologna. It was he who published, if not the very earliest, at least among the earliest anatomical plates. Notwithstanding the circumstance that he performed dissections himself, however, it is remarkable that in his descriptions of parts there are several important errors. [So difficult is it to see things exactly as they are, instead of what preconceived ideas lead persons to con- [illegible] that they ought to be.]

[illegible]tus Anglicanus, an English physician of the thirteenth century, wrote treatises on the "Preservation of Health," and on "The Virtues of Herbs." He is described as having wasted much of his time in discussing vain and subtle questions; for example, as to the destructibility of the vegetable or sensible soul, and the indestructibility of the rational soul, and so on. His theories were chiefly taken from Galen and from the Arabians.

◆

NOTE ON THE ETIOLOGY AND TREATMENT OF CHRONIC TROPICAL DIARRHŒA.

By G. HARRISON YOUNGE, L.K.Q.C.P., &c.,
Surgeon, Army Medical Staff, Meean Meer, Punjab, India.

The great prevalence and fatality of chronic tropical diarrhœa amongst Europeans in India, and the complete failure of all the usual methods of treatment in this disease, makes it a subject of great importance to army medical officers. The disease was first accurately described by Surgeon-Major A. Grant, in the Indian "Annals of Medicine," under the name of "Hill Diarrhœa."

Much difference of opinion exists as to its ætiology, owing to the fact that it is rarely seen in its first stage. In the great majority of cases it begins insidiously, and the patients rarely apply for treatment until it has become fully established.

My own experience convinces me that the disease always begins in a disordered state of the hepatic functions, and that the intestinal changes are only secondary.

In cases where I have been able to study the disease from the first I have always found that it begins as follows:—It nearly always sets in at the commencement or end of the hot weather. In other words at the time when liver diseases are particularly prevalent. The disease begins with what may be called "hepatic dyspepsia." The patient suffers from loss of appetite and morning sickness. About an hour after meals he feels sick, and there is frequently retching and vomiting of a sour bilious fluid. Distressing flatulence occurs after the food has passed into the intestines. Then loose motions occur once or twice in twenty four hours. At first, the stools vary from a pale clayey to a light green in colour, and are fœtid. Under ordinary circumstances they contain neither blood nor mucus. This stage may last from one to four months, during which time the health gradually deteriorates. In the second stage the bowels may be moved from four to six times, or oftener, in twenty-four hours. The stools are of a muddy grey or yellow colour and very frothy, closely resembling yeast in appearance; and have a peculiarly sickly odour. In all cases they show an absence, or at least a disordered secretion, of bile. At this time the tongue is of a bright red colour, and the surface is glazed. Towards the end, in fatal cases, it becomes deeply fissured and covered with aphthous patches. Emaciation takes place rapidly. During the second stage there are well-marked liver symptoms. The conjunctivæ are of a yellowish colour. There is a sense of dragging and tenderness over the right hypochondrium; and, on physical examination, the liver is found more or less enlarged.

All the symptoms show that the disease is due to an absence of the antiseptic and digestive actions of the bile. At the same time the digestion becomes impaired, and the antiseptic action of the bile ceases. This is followed by fermentation of the food in the intestines, and consequent flatulence and diarrhœa. In some cases the disease begins with acute bilious diarrhœa, the stools containing large quantities of dark inspissated bile. When this subsides the stools assume the characteristic yeasty appearance.

In still rarer cases it may be a sequel of acute dysentery. That the disease depends on derangement of the liver is further proved by the results of treatment. The only remedies useful in the first stage are those which act on the liver. Medicines, such as opium, which check the secretion of bile greatly aggravate the diarrhœa. Dr. Goodeve believed that malarial cachexia might be the direct exciting cause of chronic tropical diarrhœa. It is certainly a powerful predisposing cause, but I do not believe that it can excite the disease. Indulgence in alcohol and chill always aggravate the disease. In the first stage of "Hill diarrhœa" there are no pathological changes in the intestines; but the liver is congested, and usually softened. As the disease advances congestion of the mucous membrane of the intestines set in. This is quickly followed by effusion of plastic matter into the mucous and submucous coats. The intestinal walls become thickened, and the mucous membrane opaque. The free surface of the mucous membrane then becomes covered with minute bright red elevated points, closely resembling florid granulations. Between these the mucous membrane is of a greyish colour. The mesenteric glands are enlarged and indurated. I have often found the liver more or less atrophied, and the gall bladder distended with bile of a clear straw-colour, resembling ordinary urine in appearance, and of greatly diminished specific gravity. When these changes have existed for some time the intestinal walls begin to atrophy. The effused lymph breaks down and is re absorbed. The villi shrivel up and often drop off. Peyer's patches and the solitary glands atrophy. Surgeon-Major D. D. Cunningham has shown that the adenoid tissue entirely disappears. Professor Aitken has found well marked amyloid degeneration of the intestinal walls.

In the treatment of "Hill diarrhœa" our great object should be to cure the disease before any of these atrophic changes have occurred. The remedies to be used depend entirely on the time at which we see the disease. During the first stage we should direct our attention chiefly to the liver. I have found ammon chlorid, ℈j in inf. chirettæ, ℥j, given four times a day, most useful at this time. At bedtime I give the following pill:—℞ Pulv. ipecac., gr. j. Pil. rhei. co., gr. iij. Ext. tarax., q.s. This treatment usually at once restores the secretion of bile, and the diarrhœa ceases. I then give nitro-hydrochloric acid with some carminative as an hepatic stimulant and general tonic. Counter-irritation over the liver with ung. hydrarg. iodi. rubri is very useful. Opium is nearly always injurious in the first stage of chronic tropical diarrhœa. When the disease has reached the second stage, I have found astringents not only useless, but injurious. Sir Joseph Fayrer states that he "has found medicines useless, and that diet is the most important element in the treatment." Astringents having failed in its treatment, I was led to try pepsine in "Hill diarrhœa." I cannot find any record of pepsine having been previously used in chronic diarrhœa. The following cases show how useful it is in this disease.

CASE I.—Gunner T. S. was admitted into the Station Hospital, Cawnpore, on December 3rd, 1885, with dysenteric diarrhœa of about seven days standing having been transferred from the line of march. The motions were copious, and contained a large amount of blood, but very little mucus. The temperature was high, varying from 101·6 deg. to 104 deg. He was pale and anæmic, and very debilitated. Ordered an entirely milk diet, and brandy ℥iv. Ipecacuanha quickly stopped the dysenteric symptoms, but the diarrhœa remained unchecked. On December 10th acute hepatitis set in, and the diarrhœa became greatly aggravated. On December 13th there was extensive hypostatic congestion of both lungs. Stimulants were freely given, blisters applied over the liver, and dry cupping and turpentine fomentations over the lungs. The most powerful astringents failed to check the diarrhœa. From this to January 3rd, 1886, the patient's condition was as follows.—The bowels acted ten to sixteen times a day. The motions were copious, frothy, and yeasty in appearance. The tongue was red, irritable, and deeply fissured. The appetite was lost. The temperature was high and irregular. There were profuse night sweats; a constant hacking cough; and acute pain and tenderness over the liver. Medicines only aggravated the disease, and annoyed the patient.

On January 3rd he was so weak and wasted that he could not turn himself in bed. The tongue was deeply fissured, and covered with apthous patches. The bowels were moved about every half hour. There was a heavy cadaveric odour from the body, and he was evidently sinking fast. In consultation with Surgeon P. F. O'Connor, 6th Bengal Cavalry, I decided to try pepsine, and prescribed it as follows:—The diet consisted of four pints of milk. Half a pint was given every third hour. The temperature of the milk was raised to 100 deg., and to each half pint was added 5 gr. of pepsine. It was allowed to stand for half-an-hour, the temperature being maintained at 100 deg. It was then given to the patient. At the same time all medicines were stopped.

On January 15th all diarrhœa had ceased, he had gained flesh greatly, and he was able to take convalescent exercise. Early in February he left for England, having recovered completely.

CASE II.—Captain J. H. came under my care on 10th February, 1886. He had suffered from chronic diarrhœa for the past three years. It was most troublesome in the mornings, and he had to go to stool five or six times in rapid succession after breakfast. The disease was so troublesome that he had to give up going into society. He also had some enlargement of the liver, and constant dyspepsia. I prescribed a mild easily digested diet, and ordered pepsine, gr. v, to be taken immediately after each meal.

On February 20th the diarrhœa had ceased, but he continued the use of the pepsine for some time afterwards. He is now in perfect health, and has not had any return of the disease.

CASE III.—Gunner G. E. was admitted into the Station Hospital, Cawnpore, on the 19th August, 1886, with chronic diarrhœa. He was a slight, delicate, strumous man. He was pale and emaciated, and suffered from night sweats. The bowels were moved from ten to twenty times a day. The motions were frothy and fœtid, but did not contain any blood or mucus. Astringents of all kinds were tried, and failed. On Sept. 1st I ordered pepsine as in Case I. On Sept. 5th the diarrhœa had ceased, and when I last saw the patient he was quite well.

These cases show how useful pepsine is in tropical diarrhœa. Even in the worst cases its action is almost magical. I have now used it in a large number of cases, and always with immediate success. Previously I looked upon Hill diarrhœa, when fully established, as almost necessarily fatal. Only milk diet should be allowed, and in preparing it care should be taken that the temperature is not raised above 100 deg., as if it is the action of the pepsine is destroyed. Care should also be taken that the pepsine is quite fresh, as otherwise it is almost useless. In bad cases I always prescribe it as I did in Cases I and III, but in mild ones it may be given in powder after meals. The return to full diet should be gradual, and the pepsine should be continued for sometime after all diarrhœa has ceased. I have found pepsine invaluable in the treatment of enteric fever. It greatly increases digestion and assimilation of food; thereby lessening the diarrhœa and intestinal irritation, and diminishing the severity of the disease.

The Mortality of Foreign Cities.—The annual death-rates per 1,000 in the principal foreign cities, according to the last weekly returns communicated to the Registrar-General, are as follow:—Calcutta 37, Bombay 19, Madras 33, Paris 23, Geneva 21, Brussels 21, Amsterdam 21, Rotterdam 20, The Hague 22, Copenhagen 23, Stockholm 22, Christiania 23, St. Petersburg 26, Berlin 23, Hamburg 37, Dresden 26, Breslau 29, Munich 24, Vienna 20, Prague 31, Buda-Pesth 32, Trieste 30, Rome 28, Turin 20, Venice 27, Cairo 43, Alexandria 31, New York 30, Brooklyn 22, Philadelphia 22, and Baltimore 20.

Clinical Records.

CASES IN PRIVATE PRACTICE.

Case of Pneumonia with Metastatic Rheumatism. (a)

Under the care of David Goyder, M.D.,

Physician to the Bradford Infirmary.

The following case is interesting from the rather unusual phenomena which attended it.

W. S., æt. 26, living in the country, had twice suffered from attacks of acute rheumatism, for one of which I had attended him while resident in Bradford. On Oct. 8th, 1886, after being in a very warm room, he had occasion to go out and was exposed to a drizzling rain without the opportunity of rapid locomotion, and suffered in consequence a severe chill. On Oct. 9th and 10th pain and swelling of the knees and ankles confined him to bed, the temperature rising from normal to 102 and the pulse to 120. The administration of salicin in 10 grain doses every three hours reduced the swelling and pain of the joints, as well as the temperature and pulse; but on the evening of the 10th he complained of pain over the right chest, and developed cough, with rusty expectoration. Examination disclosed pneumonia of the right lung, worst at the posterior base. The pain in the joints had disappeared rather suddenly. The salicin was stopped, and a saline with liq. ammon. ac. administered instead. At this time the temperature was 101, and the pulse about 90. On Oct. 11th and 12th the temperature, pulse, and respirations increased, and in addition to the pneumonia a distinct effusion of fluid was detected in the right pleura, attended with well-marked œgophony. From the date of the appearance of pleuro-pneumonia the patient became extremely restless and delirious, the restlessness and delirium persisting from day to day, and rendering it difficult to keep him quiet and properly covered in bed. On the 12th a poultice was applied to the side, and digitalis added to the mixture, with the effect that next day the fluid in the pleura had disappeared. Two days after this, *i.e.*, on the 14th Oct., the delirium continuing, I was called to see the patient, and received the foregoing particulars from the medical gentleman in attendance. I found that the patient could be easily roused from his delirium, but that he lapsed directly he was permitted to be quiet and dose. The pneumonia on examination proved to be confined to the lower lobe of the right lung, but again there was unmistakable effusion into the pleura and œgophony. I advised the application of a blister to the right base, and the addition of a fourth of a grain of antimony to each dose of the mixture. On the 15th the fluid in the chest had again disappeared, the rusty sputum was gone, and the patient was bathed in a profuse perspiration; the temperature also had fallen to 99, and the pulse to normal. This gave evidence of the subsidence of the pneumonia; but, strange to say, the delirium continued, the patient being most difficult to control, and occasionally jumping out of bed when left at liberty. From the onset of the delirium the patient's pupils had been examined daily, and found perfectly mobile and sensible to light. The fact also that when roused his answers were rational, the absence of pericardial and endocardial complication, and the circumstances of the reduced temperature and pulse, rendered us hopeful that neither cerebral nor meningeal mischief were threatening. The condition of the lung, moreover, on the 16th, precluded the belief that the delirium arose from irritating reflex causes. What, then, was the cause of the persistence of the delirium? The cause, I believe, existed in the rheumatic condition of the blood. The attack had first exhibited acute rheumatic symptoms, and my previous knowledge of his rheumatic tendencies lent force to this belief. I therefore recommended a return to a modified rheumatic treatment with bromide and iodide of potassium added. Early on Sunday morning, Oct. 17th, I was suddenly called to visit him, and found that he had been excessively restless the evening before, but had gradually become quieted as night advanced: he now lay breathing heavily, with low muttering delirium, his hands outside the coverlet, and he was picking the bedclothes with his fingers; his eyes showed the pupils less sensible to light, and the pulse had sunk to 60, and the respirations to 14, the temperature being normal. In the presence of these evidences of cerebral effusion, and remembering the fitful effusions of fluid into the pleura, and their rapid absorption, I had the back of the head shaved and liquor epispasticus applied over the whole occiput and neck, and as the face appeared turgid and flushed, half-a-dozen leeches were ordered to be applied to the temples. The grave state of the patient having been communicated to the relatives, they desired a consultation with Dr. Clifford Allbutt. This was procured after a lapse of eight hours. Before proceeding to the patient's room we heard from the medical gentleman in attendance that the delirium had gradually ceased, and the patient was apparently sinking into profound coma. The pulse, however, had risen a little, and the respirations and temperature were normal. Proceeding to the room, we were all agreeably surprised to find that upon using efforts to rouse him up, he woke as if from a profound sleep, recognised his friends at once when asked who they were, and gave unmistakable evidences of perfect rationality and freedom from delirium. On examination we found that the blister had risen unusually well, and that his pupils responded perfectly to light and shade. From this time forward the patient made an uninterrupted recovery, the anti-rheumatic treatment and aperients being continued for a time, and a fairly nourishing diet being allowed. If it is asked whether the application of the blister and the leeches produced this satisfactory change in the patient's condition, I have little hesitation in saying that they did, and this opinion was unhesitatingly shared by Dr. Allbutt and the medical man in attendance. Evidently the rheumatic poison had shown an erratic disposition to expend itself on the larger serous membranes, and both in the case of the pleura and arachnoid the application of counter-irritants had diverted it. We certainly thought we had profound reasons for thankfulness at the favourable termination of the case.

Transactions of Societies.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

December Meeting.

The President, I. Mossop, Esq., in the Chair.

Dr. Goyder read an interesting case of

PNEUMONIA WITH METASTATIC RHEUMATISM,

which will be found in another column under "Clinical Records."

In the discussion which followed the reading of this case

Mr. Miall asked if the urine and the heart had been examined in this oase. These were other causes capable of producing the pleural and meningeal symptoms described which Dr. Goyder might not have eliminated.

Dr. Major said that it might appear a question whether this was a case of metastatic rheumatism with pneumonia, or whether it was an ordinary case of pneumonia complicated with meningitis. He inclined to Dr. Goyder's view. Might not the pneumonia have been produced by the salicin? He feared harm might often be done by sitting, so to speak, on rheumatism. As to the central symptoms, he was glad to observe that Dr. Goyder had applied counter-irritants and recognised the value of leeching. He had no doubt of the very great value of bleeding in these cases.

The President asked if the patient had been a temperate man?

Dr. Goyder in reply, said the urine had been frequently examined, and no trace of albumen observed, the heart had also been examined daily, and neither endo nor pericarditis existed throughout the case. He was perfectly aware of the various sources of fallacy in making his diagnosis, but adhered to the conclusion from his knowledge of the patient, who was a perfectly sober man, and from the history of the case. He corroborated Dr. Major as to the value of bleeding, and also as to the danger of the exhibition of large doses of salicin. In some rheumatic cases the results were rapid and curative, in others rapid and fatal.

Dr. Rabagliati next exhibited a patient with

SUSPECTED HIP DISEASE,

And pointed out a new and satisfactory test of the absence or presence of this affection, as contrasted with the more tedious and complicated points of diagnosis recommended in text books and in practice. His test consisted simply in flexing the thigh of the suspected side upon the abdomen (the patient meanwhile lying on his or her back), if the thigh could be completely flexed without causing the patient to raise the pelvis, the absence of disease in the hip might almost certainly be diagnosed.

(a) Read before the Bradford Medico-Chirurgical Society, December, 1886.

Dr. **MACGREGOR** explained that it was he who had sent the boy into the Infirmary. The boy had met with an accident to the hip, and though he had no hip pain he feared hip disease might follow. He was much pleased with the result of the treatment.

The **PRESIDENT** remarked that the method of diagnosis seemed original and simple, and one easily tested.

Dr. **RABAGLIATI**, in reply, said he had written to Noble Smith as to the point, and was answered that he had not previously heard of the plan, and would mention it in the next edition of his book.

Dr. **RABAGLIATI** exhibited a

KIDNEY AFFECTED WITH STRUMOUS DEGENERATION AND ABSCESS

which he had removed from a patient of whom he was presently about to speak.

Dr. **RABAGLIATI** then read the paper of the evening on

CASES INVOLVING LAPAROTOMY,

which will be found at p. 28.

In the discussion that followed the reading of this paper

Dr. **GOYDER** said that the cases cited by Dr. Rabagliati undoubtedly justified laparotomy. He had not, however, taken up (perhaps he did not intend) the subject of oophorectomy in his present remarks. Had he done so he (Dr. Goyder) was prepared to express some strong remarks on the practice. Some years ago he had seen a case of undoubted ovarian cyst, which burst into the abdominal cavity, the patient recovering perfectly, though she had since died of another affection. He congratulated Dr. Rabagliati on the result of his case of nepherectomy.

The **PRESIDENT** remarked upon the thorough treatment of the cases Dr. Rabagliati had cited. He should have been glad of his opinion on cases justifying laparotomy generally, especially those of extra-uterine fœtation.

Dr. **MAJOR** hoped the result of the operation for removal of the kidney would be satisfactory. He was pleased to know that Dr. Rabagliati had been the first in Bradford to perform nepherectomy.

Dr. **RABAGLIATI**, in reply, said he was obliged for the manner in which his remarks had been received. His paper was strictly intended to describe cases involving laparotomy. He did not intend to take up the subject. He would keep the kidney case in view, and state the result at a future time.

The proceedings then closed.

◆

DRUMINE, A NEW LOCAL ANÆSTHETIC.—Dr. John Reid, of Port Germein, South Australia, has recently published some observations and experiments which he has made on the therapeutics and physiological action of Drumine, an alkaloid obtained from the *Euphorbia Drummondii*, N.O. Euphorbiaceæ. The alkaloid is soluble in chloroform and water and with hydrocloric acid forms a hydrochlorate. The plant is a common one in Australia and frequently proves fatal when eaten by animals in a period of from 24 hours to a week. It produces a condition akin to intoxication with paralysis of the limbs. Injected subcutaneously, a 4 per cent. solution produces local anæsthesia, and when dipped into the eye, the conjunctiva soon becomes insensible to touch. Small doses do not produce any constitutional effects in man but applied to the tongue, destroys the sense of taste. It appears to affect exclusively the sensory functions and never induce convulsions. Dr. Reid believes that this alkaloid will be found very useful in a large class of cases in which cocaine is used, especially as it is free from certain inconveniences which attend the use of the latter.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 12, 1887.

PERCHLORIDE OF MERCURY AS AN ANTISEPTIC.

THE use of perchloride of mercury in dilute solutions as an antiseptic and anti-putrefactive agent has come largely into favour during the last two or three years. Introduced into France as the *liqueur de Van Swieten*, a solution of one gramme to the litre (one part in one thousand) it soon became popular with obstetricians and gynæcologists, and was used almost to the exclusion of other and more familiar agents. Its employment subsequently spread to England, principally owing to the high terms in which it was spoken of at the International Medical Congress held at Copenhagen, and is now general, not only in the department of obstetrics and gynæcology, but also in surgery.

Now corrosive sublimate is one of the most powerful germicides which we possess, and its efficacy is undoubted, whether the effect desired be the neutralisation of putrefactive changes in a retained placenta or portions of placenta, or whether the object in view be to prevent similar changes in the neighbourhood of necrosed or damaged tissues, the result may be relied upon with equal assurance. It is odourless, and this is no small recommendation after an experience of carbolic sprays and iodoform dressings, and its application is simple and inexpensive. These qualities account for the readiness with which it has been adopted in the treatment of affections where it is of primary importance to forestall or cut short changes which would be locally undesirable and constitutionally dangerous.

It had, however, not long been in use before it was noticed that the good qualities which had secured for corrosive sublimate a rapidly acquired excellent reputation were not without some drawbacks. It was very soon remembered that if corrosive sublimate were possessed of a promptly fatal influence on the various forms of bacillary and bacterial existence, the same powerfully toxic properties were apt to manifest themselves on the tissues and on the economy of the patient treated by means thereof. It was found, moreover, that even apart from its intoxicating properties, it was highly irritating. and was apt to cause excoriation of even healthy tissues, and this when employed in the form of Van Swieten's liquid, containing only one part in a thousand. The attendants in the obstetrical wards of the various hospitals in Paris where its use had become general soon became familiar with the rash which its use as a disinfectant of the hands not unfrequently gave rise to, and a certain number of violent local inflammations following its use as a dressing demonstrated the necessity of caution in this respect. The matter went a step further when statistics were published showing that a rather appalling number of deaths were to be attributed to the absorption of the poison when injected or used as an irrigation.

The fact is, that solutions of corrosive sublimate are readily absorbed, and hence the greatest caution is requisite in injecting it into cavities or in allowing it to remain in contact with living tissue for more than a very short space of time. The remaining liquid should be carefully washed away, and the quantity used should be small. The proportion of one part in one thousand is too great; one in two thousand should be the maximum strength employed, and even then it should be used as a wash, and not as a dressing.

A case was reported a few weeks since in which the injection of a comparatively small quantity into the rectum in lieu of the vagina gave rise to symptoms of profound intoxication, to control which was a matter of the greatest difficulty and risk. It is principally in cases where the solution has been allowed to sojourn in a cavity such as the uterus, vagina, rectum, or abscess cavity, that untoward results are to be apprehended. It is to be remarked in reference thereto that the symptoms of acute poisoning by corrosive sublimate are severe but misleading, especially during the puerperal period, when they are often undistinguishable from those common at that epoch. Violent headache, vomiting, sanguineous diarrhœa with rectal and vesical tenesmus, some or all of them occur, and the characteristic affection of the gums may be absent from the suddenness of their onset, a certain lapse of time appearing to be necessary for the gums to show signs of mercurial influence.

To sum up, perchloride of mercury is an useful but powerful agent. It is invaluable as a disinfectant and antiseptic, but its employment is only permissible on condition of due caution in regard to the strength and circumstance of its use. More rapidly and effectually than any other agent it checks offensive discharges from the uterus due to decomposing matter, and if proper precautious be taken, with perfect safety. Absorption only takes place under certain well-defined conditions which it is easy to foresee and prevent; but it behoves every surgeon and obstetrician who uses it to keep a sharp look out for the symptoms to which such absorption gives rise, and which should be the signal for recourse to more dilute solutions, or even to another and less toxic agent.

THE OUTLOOK IN SCOTLAND.

SELDOM has a year opened with greater promise of progress than the present. By a strangely fortuitous coincidence things have been coming to a head in different directions at once, and, to-day, more distinctively than for long, the minds of men are intent waiting for the moving of the waters. The Universities of Scotland are looking forward once again to the early introduction of an Universities (Scotland) Bill. A Conservative Government has generally been regarded as an excellent framer of University measures, and in Mr. Balfour's hands the University interests may be considered in good keeping. The Scotch Secretary is no novice in educational work; his speeches show him to be a man well versed in the details of University requirements, while preserving the fullest sympathy with the honourable traditions of Scotland. It may be hoped, then, that the suggestion for summarily closing accounts with the Scotch Universities by the introduction of a finality clause—which has discredited more than one previous proposal—has been made for the last time. It may be expected, moreover, that in handling the difficult problem the Government will see its way to approach the whole subject, unfettered by the blinding and ill-fated influence of class prejudice. The development of the Universities must be guided into right lines, apart from considerations of private and vested interests. Never was there a more opportune occasion for the widening of the University basis, and never did so much depend on the wise solution of the problem, how best to effect this. The question of administration and direction will have to be reconsidered entirely.

While much of praise must be accorded to the Senates of the Scotch Universities for the way in which they have discharged the onerous duties in the past, it must be admitted, as the gravest anomaly that the teachers in a national institution should have practically the entire say in the arrangement of the curriculum and the administration of the funds. Questions of the most delicate nature necessarily crop up from time to time, which *prima facie* could not fairly be settled by such a tribunal. It is better, therefore, that men, whose appointment has not been influenced by known business capacity, be saved from these trying positions, and their full energy preserved for the prosecution of those special studies to which they are more naturally called. The Universities can never be in want of good governance when they can fall back on the University Court and Council. Neither of these bodies, as it seems to us, has received in times past that place which the framers of earlier University enactments intended they should have. In any fresh bill the correction of this mal-execution of previous legislation must be obtained, and the powers of the different bodies more accurately defined. Only when this is fully and satisfactorily arranged may we expect to have a fair consideration of other grave questions, such as the extension of the University curriculum, the modification of degree examinations, the increase of extra-mural teaching, and the improvement in the status of University assistants.

In addition to those wider problems, the Government will have to consider the special claims of the different Universities. More especially it must have regard to the position of the venerable University of St. Andrews. We refer in particular, for the present, to the possibility of raising the status of St. Andrews as a medical school. With the rise of medical colleges and schools in so many of our larger English towns, it is most natural that attention should have been attracted to Dundee, where already a University College in Arts and Science exists. There is, moreover, an excellent and extensive infirmary, and a large pauper and labouring population. Affiliated to the University of St. Andrews, Dundee affords the most ample scope for the development of a first-rate curriculum in medicine. Recent reports clearly suggest that both the aged University and her younger commercial neighbour are fully alive to the advantages which might be expected to accrue to both by such co-operation. We do not think the time far off when the experiment must be made. The University of Aberdeen, too, will have fresh demands on Her Majesty's Minister for Scotland. It is a notorious fact that the space at the disposal of the teachers at Marischal College—the medical school in Aberdeen—is far below the necessities of the students. There is not a department, with the exception, perhaps, of the anatomical, which can be regarded as even fairly housed. Meanwhile, the University authorities have not been idle. Much of the suitable adjacent property is either actually or potentially in their hands. With the help of a sufficient grant from the Crown, such extensive changes are now possible as will place the Northern School of Medicine on a level with any of her more fortunate compeers in the South.

The extra-mural schools of medicine, both in Edinburgh and Glasgow, have done much to improve the teaching in these centres, and it is to be hoped that, in future legislation, more distinct recognition will be taken of this factor in the success of the Northern medical schools. Their united action, the success of their approaches to Government, and the feeling expressed by the members of the General Council of the University towards them are the best augury of increased prosperity in the future. The Royal College of Physicians of Edinburgh has made an important move in advance in the projected establishment of a research laboratory. If wisely directed, this should prove one of the most powerful factors in the higher development. The College has always been supposed wealthy, but hitherto there has been little evidence of the value of her wealth outside the favoured circle of her Fellowship. The projected laboratory would presumably be open to accredited workers apart from any restriction. In any case, the licentiates and members could hardly be excluded from participation in the advantages of so valuable an institution. We wish the College God speed in the admirable enterprise, and may be allowed to express the hope that the Fellows will see their way to the establishment of research scholarships or prizes as an almost necessary complement to the erection of a laboratory.

For the first time, the general body of the practitioners in Scotland will, this year, have a distinct say in the suggestion and adoption of measures affecting their private and public interests. The representation of the practitioners generally is, meanwhile, an experiment, on the result of which will depend the continuance and the possible extension of the principle. We once more congratulate the profession in Scotland on having obtained the services of so thoroughly capable a man as Dr. Bruce of Dingwall. The Universities, Colleges, and Corporations are each most efficiently represented. With much to be done and so excellent men to do it, we look forward with hope to the results of the year which has just begun.

◆

THE APOTHECARIES' COMPANY AND THE IRISH CONJOINT EXAMINATION.

We understand that the Fellows of the Irish College of Physicians have by a majority of seventeen to four peremptorily rejected the suggestion of the College of Surgeons that the relation of the Apothecaries' Company to the conjoint examination should be reconsidered, in view of the strong opinions expressed by the General Medical Council on the subject. "Quem Deus vult perdere." If these seventeen gentlemen think more of their high horse respectability than of the interests of their College, still less the interests of the profession, and least of all, the interest of the public, so much the worse for themselves. We do not, however, see any reason why the Fellows of the College of Surgeons or the members of the General Medical Council, or the Lord President of the Privy Council should take the same view, and we certainly hope and expect that one or all of these appeal tribunals will have the firmness to disregard the aristocratic sentiment of these gentlemen, and insist upon the conjoint examination for Ireland being made one and undivided—complete, compact, and comprehensive. The Council of the Irish College of Surgeons has—as we think most foolishly—been led, by their anxiety for a conjoint examination at any price, into a contract with the College of Physicians from which they cannot now honourably draw back, but the approval of the Fellows of the College has not yet been asked, and we cannot believe that they will, under any circumstances, give their assent to an arrangement by which the College will be harnessed in badly fitting harness, and with an unwilling mate, and be obliged to race for existence under a heavy handicap against a nimble competitor who carries no such burthen. If, however, the Fellows of the College of Surgeons did agree to such an arrangement, it would become the duty of the General Medical Council, in the interest of medical education, and of the

Privy Council in the interest of the public, to prevent such a contest of licensing in Ireland, and the College of Physicians may be assured that those bodies will be called upon to do their duty if it be necessary to invoke their interference.

But if the Irish College of Surgeons is obliged to proceed with its conjunction with the College of Physicians, we do not know of any reason why it should not also enter upon a similar and separate conjunction with the Apothecaries' Hall. The Medical Act of 1886 specially legalises such a conjunction, and we fancy the Apothecaries' Hall would be willing to co-operate heartily, and thus it would be open to the student to obtain the qualifications of L.R.C S.I. and L.K.Q.C.P.I. at a high price, or the combination of L.R.C.S.I. and L.A.H. at a less expenditure.

At any rate, we must repeat that an arrangement which would leave the Apothecaries' Hall in a position to act independently in competition with the other Irish licensing bodies cannot be tolerated.

We understand that some of the Fellows of the Irish College of Physicians are not pleased at our having published last week an abstract of the First Report of the Irish Conjoint Examination Committee. We really cannot adopt their view. The document was printed in considerable number, and was in the hands of at least fifty persons in Dublin outside the Committee; nor was it marked as confidential, nor did it bear any appearance of privacy. We do not understand any secrecy in such matters, which, affecting largely the public interest, the public have a right to know, and, moreover, we have been made to feel by abundant experience that the correspondents and editors of our medical contemporaries are not restrained from publication by the theory of "confidential communication" which we are expected to respect. Therefore we must avow our intention of continuing to publish any interesting information which we can obtain without breach of confidence or of official duty.

Notes on Current Topics.

A Judicious Blend.

A would-be suicide was charged at the City of London Police Court last week with having taken poison. The particular agents employed appear to have been a curious mixture of sugar of lead and sulphate of zinc. If the conjunction were due to purely fortuitous circumstances the accused is to be congratulated on the fact that there is a providence which shapes our ends. An accomplished chemist could scarcely have devised a better formula for the use of desponding persons who do not altogether care to shuffle off the coil. The woman—for the culprit was a female—was stated to have been insensible when discovered, but doubtless this partook of the nature of the sudden paralysis which has been known to affect duellists immediately on the discharge of the pistols even when, thanks to the prudence of the seconds, nothing worse than wadding was to be feared. Although no very dreadful results were to be apprehended from the ingurgitation of the mixture, its effects on the stomach may very possibly have been such as to render the genuineness of the regrets which she expressed very probable. We venture to hope that these unpleasant reminiscences will suffice to deter this unfortunate person from any further attempts on her life, wretched though it be.

Olfactory Acuteness.

An interesting contribution was recently made by Messrs. Nicholls and Bailey to *Nature* giving the results of experiments upon the relative acuteness of the sense of smell in individuals. A series of solutions of oil of cloves, nitrite of amyl, extract of garlic, bromine, and prussic acid were prepared by successive dilutions with water until the limit of perception was reached, and then the solutions were placed indiscriminately and submitted to a number of persons of both sexes to classify them properly by the sense of smell. The results showed that on the average the sense of smell was much more delicate in the males tested than in the females; but the degrees of keenness ranged widely as between individuals. Thus three male observers were able to detect one part of prussic acid in 2,000,000 parts of water, though its presence was not revealed by a chemical test; but others, of both sexes, could not detect prussic acid in solutions of almost overpowering strength. The following figures give the average limit of delicacy of perception:—Cloves—Males, 1 in 88,128; females, 1 in 50,667. Nitrite of amyl—Males, 1 in 783,870; females, 1 in 311,330. Extract of garlic—Males, 1 in 57,927; females, 1 in 43,900. Bromine—Males, 1 in 49,254; females, 1 in 16,244. Prussic acid—Males, 1 in 112,000; females, 1 in 18,000.

Foreign Bodies in the Œsophagus.

During a discussion which ensued on the reading of a very excellent paper on a case of gastrotomy, at a meeting of the Medical Society of Suffolk, U.S.A., by Dr. M. H. Richardson, several points of practical interest were incidentally dwelt upon. The operation in question was performed for the removal of a tooth-plate looped in the lower portion of the œsophagus, and consisted in an opening large enough to admit the forearm of the surgeon being made in the abdomen, through which the hand was passed to the stomach, this likewise being freely opened, and the first and second fingers then passed through the cardiac orifice of the œsophagus until the plate could be reached and extracted. It transpired that difficulty had been experienced in introducing a probang down to the foreign body while the patient lay recumbent, and Dr. Cheevers, who discussed the paper, narrated his own similar experience in five instances in which he had performed œsophagotomy. The difficulty met with consisted in the probang slipping into the glottis, and neither of the operators could afford an adequate explanation of it. On the subject of rectal feeding it was found on a comparison of observations that patients nourished by enemata after such operations most often complained of hunger sensations, but thirst was sometimes found to be the more prominent craving. Dr. Cheevers having mentioned that it was a difficult undertaking to draw out the stomach sufficiently for all subsequent manipulations to take place extra-abdominally, Dr. Richardson contended that this measure could easily be carried out, according to his own experience, and further gave it as his opinion that operation should be at once resorted to after failure to dislodge the obstruction by means of the probang, and that it should be completed at a single sitting.

Deodorisation of the Dead.

IT is rather an unsavoury subject to allude to, but like the ancient mariner, we cannot do but say. In this country the interment of deceased persons is often postponed until decay's effacing fingers, have swept the lines where beauty lingers, and even a trifle beyond. The result, especially when climatic influences aid the process, is to produce a condition of things, when at last the funeral does takes place, which is injurious and repulsive. In the absence of any regulations as to the epoch at which deceased persons must be interred, it would be a salutary measure to insist on one or two elementary precautions with a view to minimising the effects of the emanations which are not only distinctly perceptible in the immediate neighbourhood of the corpse, but even when it is being conveyed to the place of burial. One simple means is to fill the coffin with sawdust impregnated with some cheap deodoriser, such as sulphate of zinc.

Society for the Study and Cure of Inebriety.

AT the quarterly general meeting of this society held in the rooms of the Medical Society of London on the 4th inst., the president, Dr. Norman Kerr, in the chair; Mr. Tudor Trevor read a paper on the Prevailing Indifference to Inebriety. Dr. H. W. Williams, Mr. Hilton, Mr. Raper, Mr. Gustafson, and Mr. Frederick Trevor took part in the discussion.

A Disreputable Occurrence.

MR. WILLIAM HENRY DAY, of Grove Dale, East Dulwich, in company with two other individuals, was arraigned at the Westminster Police Court last week, charged with being drunk and disorderly, and with causing wilful damage. It seems that "Dr." Davenport, whose name, in connection with that of Dr. Day, has been brought prominently before the public in connection with the illegal practice of medicine by the former, and the improper signing of a certificate of death by the latter, has become an object of animosity to the friends of his alleged employer, Dr. Day. Whatever the grievances of the latter may be, they certainly did not justify his friends inflicting wilful damage on Davenport's property—property which, we may remark, incidentally was said to belong to Dr. Day, but which in the present case seems to have reverted to Davenport. The tenure is evidently insecure! The magistrate characterised the proceedings as most disgraceful, and sent the prisoners to prison for a month. We would venture to suggest to Dr. Day that "evil communications corrupt good manners," and that the unholy alliance of a qualified practitioner with a man not duly licensed to practise medicine may be productive not only of disagreeable incidents at inquests held on the bodies of patients attended by the latter, but also of other and even more serious detriment, especially when one's friends are addicted to the abuse of "drink and obscene language."

The Crown Representative for Ireland.

WE are in a position to assert that all the published statements to the effect that an appointment has been made to this office were, to say the least, premature, and that at the time of our going to press no official intimation has been made on the subject. We understand, furthermore, that the mention of Sir George Owens as a candidate for the office was also incorrect, that gentleman not having submitted any application to the authorities. This error arose apparently from a paragraph communicated to the London *Daily Chronicle* by its Irish correspondent, and copied thence into a medical contemporary.

Payment of Dispensary Substitutes in Ireland.

WE learn with satisfaction that Dr. Bolton, of Ballickmoyler (Carlow), has, last week, recovered in the County Court the fees due to him for acting as *locum tenens* for Dr. Hearne of that district during illness. The Dispensary Committee retained Dr. Bolton's services in official form, but the guardians refused to pay, on the ground that they had, at Dr. Hearne's appointment, passed a resolution that they would not pay substitutes. Dr. Hearne was prepared to repudiate, in the witness-box, any acquiescence in such resolution, but the judge did not consider his evidence necessary. The judge held that there was a clear contract between Dr. Bolton and the Dispensary Committee, and that the guardians must pay and if they thought they could prove that Dr. Hearne had contracted with them to pay his substitute, might try their remedy against him. This case was fought by the Irish Medical Association on behalf of Dr. Bolton to establish the princible that the guardians could not, by any resolution impose on the dispensary medical officer the obligation to pay his substitute during illness, and the result is very satisfactory. The Irish Medical Association has thus scored a valuable addition to the code of protective law already established by them on behalf of the Poor-law medical officers of Ireland.

Stomach Digestion.

OPPORTUNITIES for studying gastric digestion through fistulous openings into the stomach are, thanks to modern surgery, more frequent than formerly. This is important, as the physiology of digestion, as understood at the present day requires more than the classical instance of Alexis St. Martin to place it on a sound experimental basis. Such a case with experiments *ad hoc* is recorded in a revue scientifique by von Herzen, of Lausanne. The subject was a man, æt. 28, on whom gastrostomy had been performed for occlusion of the œsophagus. The observations made were as follows:—Bile always appears in the stomach during digestion, but generally only in the later stages. The amount of H Cl amounts to 1·8 to 1·9 grm. pro litre; it increases during digestion and reaches its maximum in the third hour. Sodium chloride appears rather to diminish the amount of acid. When the stomach was empty in the morning, but little pepsin was found, and a large amount of propepsin; peptogen accelerated digestion. In the first hour, of a quantity of albumen introduced, 2 per cent. was digested without peptogen, 12 per cent. with it. In the second hour, 23 per cent. was digested without, 45 per cent. with peptogen. In the third hour, 51 per cent. without, 76 per cent. with peptogen. These results agree with those obtained by Schiff. Chloral, quinine sulphate, and above, all potassic iodide, retard digestion. The author would forbid red wine in disturbances of digession, but would recommend bouillon and dextrine; blood fibrine is also indicated in many cases.

Antifebrine.

Professor Gerhardt has employed this remedy in ten cases of articular rheumatism, in doses of 3 grm. three times a day. In five of the cases (not recent) it was of no service. In five others (quite recent) it cut the disease short in one case, in two others it was almost completely successful, and in the two last its action was only moderately so. He likens the action of the new drug to that of antipyrine, to which it has, however, no relation chemically.

Educated Brutality.

Under this somewhat ambiguous heading the report is given in an evening contemporary of the trial of a physician and his wife, for cruelty to their child. It seems that the child, a girl, had been guilty of some inattention to lessons and in consequence, the defendant and his wife resorted to corporeal punishment, by means of a riding whip to an extent, which, we cannot but consider excessive in the extreme. The chastisement lasted about half an hour, and was so severe that the child fainted immediately afterwards. A doctor who was called in by the police, testified to the marks of injury being the result of considerable violence, and the defendants were fined £25 each. The occurrence is a deplorable one, particularly as the defendant is a practitioner of some standing.

A Cholera Cemetery.

The excavations on the Middlesex side of the Thames for the erection of the new Tower Bridge will necessitate the removal of the remains of persons who are interred in the small cemetery at the eastern end of the Tower. It was at first thought that some persons of historic note were buried there, but it appears that the ground was first set apart in 1832 during the first visitation of cholera for the interment of persons who had died of the disease in the Tower, and since then no bodies have been buried there. All danger of infection has probably been destroyed by the natural forces at work during so long a period of time, Possibly it would be of interest if Professor Koch or some other worker in the department of bacteriology were furnished with a sample of the mould for the purpose of instituting a search for the famous comma bacillus who still lingers on a frail existence as the cause of this terrible disease. There are diseases, the infection of which persists for an unknown but certainly extended period of time after burial, and disturbance of the ground in which the remains have been interred have been followed by outbreaks of the disease. Whether cholera be one of them we are not in a position to say; let us hope not. From another point of view it is satisfactory to contemplate the return to active service of land set apart so long since in response to special and passing needs. We should much like to see several other intra-mural cemeteries change their present wilderness-like aspect for another and more attractive appearance. While there can be no reason to object to the construction of bridges on such sites, they are unfitted for the building of houses and would probably be best employed, as has already been done in several cases, in providing gardens or playgrounds for the people.

The Perils of Kitchen Boilers.

The risk which attends the use of the better forms of kitchen boilers in which no provision is made for accidental stoppage and renewal of the water supply, has unhappily been but too well demonstrated during the past week. Two fatal cases have been reported, one at Acton and the other at Shepherd's Bush. In both, the cause was the same, viz., stoppage of the water supply in high pressure boilers from frost, and sudden entry of water into the heated boiler when the ice was thawed by the heat. It is to be hoped that these untoward occurrences will be instrumental in calling the attention of the proper authorities to the need of laying down regulations with a view to their prevention. The risk can be obviated by several simple precautions. One is the employment of a plug made of fusible metal, so as to melt when the heat exceeds a proper limit in consequence of the want of water. Another would be to provide means for cutting off the water supply when its unexpected return would involve risk of explosion. The latter method is less to be recommended from the fact that it is not automatic in action, and that its efficacy is dependent on a foresight and intelligence upon which we are not always entitled to rely. Means of some kind ought to be insisted on, and that promptly. It is little less than scandalous that boilers should be permitted to be constructed of a kind which renders serious and even fatal accidents inevitable under a concourse of circumstances which are almost certain to present themselves sooner or later. Probably, no code of rules will ever prevent people searching for gas leaks with a lighted candle or match and the utmost that can be hoped for, is that experience may in the long run, act as a deterrent. The prudence begotten of experience, however, can never be a perfect safeguard since, for many reasons, not many persons get mixed up in a gas explosion twice it their lives. As regards boiler explosions, on the other hand, the blame rests entirely on the architects and builders, who from ignorance, indifference, or motives of economy, employ apparatus which are as dangerous as the undischarged bomb shells which careless people have been known to use as anvils or playthings. The prophylactic treatment of shortcomings such as these would be to make their employment of boilers without adequate means of protection, an indictable offence, or at any rate to prevent as far as possible their use.

The College of Physicians of Philadelphia celebrated the centennial anniversary of its foundation last week.

Preventible Mortality.

IN the Registrar-General's return for the past week for the metropolitan area, no less than *thirty-five* children under one year of age are stated to have died from "suffocation." This, we presume, may be taken to mean asphyxia from overlaying or other form of accidental or negligent deprivation of air. Such a figure is simply appalling, the more so as such occurrences are in the majority of cases of an eminently preventible nature. It is, however, difficult to suggest a remedy for this condition of things beyond giving publicity to the lamentable frequency with which such accidents happen. No repressive measures would appear to have any chance of success, and would only add to the distress which the unfortunate result inevitably causes. A mild censure is all that the coroner can offer and even this cannot always be given.

What is Beer?

THE analysis of beer and malt liquors generally has always been difficult and unsatisfactory in consequence of the want of a legal definition of what beer is or should be. This difficulty has recently found expression in the quarterly report of Dr. Bernays, the analyst to the Camberwell Vestry, who, commenting upon two ales and two porters which had been submitted to him for examination, said he should no longer continue to report that they were of the nature, substance, and quality demanded because he did not know what people expected when they asked for beer. Some only would be said to be allowed by law, and were therefore of the nature of beer. When the article was brewed with London water and contained over fifty grains of the chlorides of potassium and sodium, it was evident that these salts did not come from malt and hops, but from the common sugars employed. Such quantities of liquorice were found in certain samples of porter that it must be altogether a matter for taste as to what people required in their drink. He added that beers and porters were in any case very uncertain alcoholic drinks.

The Sale of Practices.

THE sale of practices or shares of practices, so common in this country, is nevertheless by no means universal. Not long since an action was brought at Paris to recover a sum of money alleged to be owing as the price of a sale of this kind. The plaintiff was non-suited on the ground that the *clientèle* of a physician was not a saleable property, and therefore that the money agreed to be paid in consideration thereof was not recoverable by law. Such a decision is apt to surprise one in view of the large sums of cash which change hands on this side of the channel for such considerations. A practice may or may not legally be a saleable property, but it is pretty certain that practices are really transferred for a pecuniary consideration, and although all the patients do not transfer their affection and confidence to the acquirer of the practice, yet generally speaking, a very large proportion do so. The fact is that the goodwill of a practice is bound up to a great extent with the house, and many people having once acquired the habit of going to a particular house continue to do so irrespective of its inhabitant, provided he be a medical man.

Extirpation of Goitre in Berlin.

HERR WEIDEMANN has collected and published the statistics of the operation as performed in the Augusta Hospital, Berlin, between the years 1880 and 1885. Extirpation was performed 25 times during this period, 22 of the patients being females and 3 males. Seven of the patients were in the second decennium, six in the third, four in the fourth, two in the fifth, five in the sixth, and one in the seventh. With the exception of three cases all were from one region, viz., the Mark provinces (of which Berlin forms the centre), Uckermark and Neumark being the most numerously represented. In later years an increase in the number of cases had been noticed, and especially in Berlin. In two cases the goitre was cancerous in its nature. In three cases a history of heredity was observed. One case showed all the symptoms of Basedow's (Graves') disease. In this case the symptoms disappeared after operation. The author sees in this an indication of the correctness of the view that there is no such entity as Basedow's disease, that the first step is goître, the other symptoms being produced by pressure of the tumour on the sympathetic During pregnancy the tumour not only underwent a temporary enlargement, but one that to some extent was permanent. In one case that had existed from youth, a rapid development took place after the "change.' In almost all the females affected the menses appeared late. Three women had aborted, and at periods when the tumour caused inconvenience, but whether in consequence of the respiratory troubles could not be determined. The author was, however, disposed to look upon goître as a factor in the late appearance of the menses, and also in the production of the abortion. At the time of operation, asphyxia had occurred in three cases, which necessitated tracheotomy in every case. The cause of the sudden asphyxia lay in atrophy of the tracheal cartilage, and consequent flattening of the trachea from pressure. In seventeen cases partial resection of the "gland", was performed, and in every case the patients are now perfectly well. Of six total extirpations, two died of secondary hæmorrhage, one patient had to wear a tracheal tube in consequence of previously existing paralysis of the recurrent nerve. In the case of a boy, fourteen years of age, a pronounced cachexia has since developed with myxœdema. Both the cases of malignant disease died, one from recurrence of the disease a few months after the operation, the other shortly afterwards from "mediastinitis."

The Conception of Male Children.

IN a recent number of the *Archives für Gynæcologie* Dr. Camillo Fürst, of Graz, contributes an interesting paper to the frequently discussed question of the determination of sex. The author first treats of "the time and causes of the determination of the sex in general," and endeavours to show that a surplus of male conceptions in the working classes and country inhabitants is always taking place, as compared with the well-to-do people and the inhabitants of cities; likewise that we can look for the surplus of male infants during hard times and the resulting rise of food prices, and before the ultimate extinction of a race. If a deficient nutrition of the procreators produces a surplus of male children, our author continues to argue we can be certain that also the state of nutrition of the fecundated ovum, especially shortly after conception, will influence the sexual differentiation. And as after menstruation the vessels of the genital organs assume an ischæmatous character—forming the so-called post-menstrual anæmia —Fürst concludes that conception taking place immediately or shortly after menstruation will give a surplus of males on account of a relatively bad nutrition of the fecundated ovum. To strengthen his theory, the author utilises the statements of women confined in maternities, who mostly with astonishing certainty could remember the end of the last menstruation and the day of conception. The statistics of the mentioned institutions show a very considerable surplus of male children for the first four or five days after menstruation, and a surplus of female ones for the succeeding period.

Nitro-glycerine in Suspended Animation.

An interesting case is reported in the *Sei-i-kwai*, medical journal of Japan for November, of the resuscitation of a woman apparently dead by the hypodermic injection of nitro-glycerine. A Mrs. Fraser, of Chicago, a few days after childbirth, sank from collapse, and life was believed to be quite extinct. Dr. M. H. Sackersteen, who was in attendance, after having administered various remedies, was about to abandon the case as hopeless when it occurred to him to try nitro-glycerine. He injected ten drops of a solution into a vein. A minute elapsed before his patient gave a slight gasp; in another minute this was followed by three or four gasps, and after the third and fourth minutes the pulse was felt, and the heart was distinctly heard; a flush came over the face of the patient, the eyes opened, and the muscles, which had assumed the rigidity of death, gradually relaxed, and she became conscious. In a few days Mrs. F. made a good recovery. It has been suggested that the hypodermic injection of nitro-glycerine should be tried in all cases of collapse or death from an overdose of chloroform and shock from surgical operation. Martindale, in his very useful "Extra Pharmacopœia," gives several forms for the administration of nitro-glycerine in solution, hypodermic injection when the patient cannot swallow, or drops, tablets, &c., all being perfectly safe, stable, and palatable. His tablets or troches are quite attractive in appearance, and cannot be distinguished by taste from ordinary chocolate creams. No child would refuse them.

Mr. Jaffray, the munificent founder of the Jaffray Suburban Branch of the Birmingham General Hospital, has received during the past week £1,000 as a contribution to the endowment fund from an anonymous donor.

An epidemic of measles of a severe character has broken out at a village named Sebastopol, Monmouthshire. There are over a hundred cases under medical treatment, and no fewer than twelve children are lying dead, as many as three in one house. The neighbouring medical officers have obtained permission to close the schools should the epidemic attack their districts.

As a result of the collections on Hospital Sunday in Birmingham for 1886, the Committee have been enabled to hand over to the Birmingham General Hospital the sum of £4,231.

France

A RETROSPECT OF 1886.

[FROM OUR OWN CORRESPONDENT.]

It cannot be said that the past year has been one of those in which some remarkable and special advance has been made in either of the three branches of the profession or their subdivisions. But at the same time it cannot be denied that some good information was obtained in several of those diseases which needed much *éclaircissement*, and a better understanding of several affections of the domain of medicine and surgery is the result of diligent research throughout the year. Microbes, or bacilli, have been incriminated in most cases, and in some with a good deal of reason. The *rôle* they play in the etiology of typhoid fever is now beyond dispute, and consequently it is not surprising that the treatment is based on antiseptic principles. Enemas of phenic acid twice a day, and the administration of salicylic acid are frequently ordered. The German method, Brand's, has not found much favour in France. Good opportunity was afforded two years ago by the epidemic which ravaged Paris, to study the best form of treatment, but no well-defined plan could be found. A. M. Demange proposed the injection of fifteen drops of ergotine when the form is cardiac or syncopal. He explained the influence of the ergotine supposing the condition of the patient was due to weakness of the heart, and that the drug restores its tonicity. Phthisis has attracted considerable attention during the year, the question of contagion has long occupied the minds of the leading members of the profession, and last year the Société Medicale des Hopitaux sent out 10,000 circulars on the subject to medical men, asking for their experience on the subject Unfortunately only eighty-three of that large number sent replies. Fifty-seven affirmed that pulmonary tuberculosis was contagious; thirteen as strongly denied it, and the remainder left it an open question. The number of cases brought forward was 439, of which the half was inscribed as cases derived from direct contagion Such was the report which M. Vallin laid before the Société. It would appear that although heredity plays an undoubted preponderating *rôle* in the malady in question, the child runs a much greater risk when the mother at the time of conception is tuberculous. When the father alone is phthisical he often escapes Hereditary consumption the more frequently declares itself at a tender age, while the affection appearing in middle life is generally acquired. The Conseil D'Hygiene issued also during the year notices on the danger of allowing the expectoration of tuberculous patients to lie about on the floor or the clothes, as when it becomes dried the dust, charged with bacilli, enters the lungs of the other occupants of the room and set up that flame which, up to the present, medical science has been powerless to extinguish. A competent medical authority told me that one in every six persons in France dies of phthisis. The treatment of consumption has also received attention during the year, iodoform administered in quills being in favour with a good many, and especially with Dr. Huchard, of Paris, who is no mean authority on the subject, and who unites it with creosote. Unfortunately no advance has been made in the treatment of croup or diphtheria, the abundance of agents recommended proving the little faith they command. It is true that a Dr. Delthil made no little noise about the inhalation of a mixture of turpentine and oil of tar (one-third of the former and two-thirds of the latter). He brought forward three cases which were treated successfully by this method; but in other hands it did not seem to prove so successful. All that can be said about it is that *he* succeeded where others failed. M. de Gassicourt was commissioned by the Société Medicale des Hôpitaux to examine into the case, and he read his report before the Society, in which he declared that having tried it in twelve cases of croup he was completely disappointed. None of the cases were benefited, on the contrary, he considered that the black smoke arising from the mixture could not be otherwise than injurious to the children. Other members also made experiments about the same time, and their unanimous verdict was, unfortunately, pronounced against the treatment as wholly inefficacious. A new and very simple treatment of whooping-cough has been highly recommended by several good authorities. It consists in the administration of the ordinary oxymel of squills by teaspoonful every ten minutes, at night five times successively. In three or four days the attacks are much diminished, and yet a few days and the affection disappears altogether. Thanks to Dr. Huchard, angina pectoris which was considered hitherto as incurable, is now amenable to treatment. Palliative remedies, such as nitrite of amyl, iodide of ethyl, bromide of potassium, nitro-glycerine, &c., were the only resources of the practitioner against that terrible malady. It remained for Dr. Huchard to prove that in the iodide of sodium we have an agent which acts almost as a specific when properly persevered in. And this he has done in the most assured manner, so that henceforth angina pectoris may be classed amongst those diseases which are considered curable. Of hydrophobia and Pasteurism, we heard but little during the last quarter of the year. Are public minds becoming less enthusiastic about vaccine inoculations? is a question which requires an answer, but considering the instability of the French character, it would not be surprising if the people have turned their thoughts to something now more attractive. Be that as it may it is no less curious that for some considerable time hydrophobia has occupied very little attention. M. Pasteur, who deserves the greatest credit for his indefatigable researches, and the deepest gratitude from his countrymen, seems himself to have been a little disappointed at the result of some of his cases. Several deaths occurred in spite of every precaution. No doubt the number of persons who had recourse to him might well be regarded as enormous. But were they all otherwise condemned to certain death? Were all the wounds those of rabid animals? These questions are suggested by reflection on the subject, and perhaps satisfactory answers might be found. In any case, medical men's minds are not fully satisfied as to the effect which M. Pasteur claims for his treatment, and it must be for time to clear up the many doubts which exist. In the department of surgery there is very little to record for the past year. Prof. Olier, of Lyon, still holds on to osteo-clasy, which he prefers to resection in the treatment of genu valgum. The supra-pubic operation for stone is meeting with much favour, and a slight attempt has been made to explore the lungs. Pneumotomy and drainage of the organ have given some satisfaction in cases of pulmonary abscess, and injections of a very weak solution of corrosive sublimate have been successfully employed by Dr. Gouguenheim.

Germany.

[FROM OUR OWN CORRESPONDENT.]

Treatment of Cancer of Uterus by Hysterectomy.—In a paper on the above subject in the *Nouvelles Archives d'Obstetrique et de Gynæcologie*, Kœberle gives his views on a matter about which considerable difference of opinion exists amongst gynæcologists, and in regard to which a corresponding difference of practice prevails, some preferring total extirpation of the uterus when the cervix only is implicated, and others contenting themselves by removing the diseased part only. Kœberle is opposed to hysterectomy in carcinoma of the vaginal portion, and thus lends the weight of his authority to those who limit hysterectomy to exceptional cases. He only recommends the graver operation for those cases in which the body and cervix are diseased, and in which the vagina, appendages, and lymph glands are intact. Total extirpation, whether performed from the vagina or by laparotomy, affords but a grave prognosis both as regards the operation itself and the chances of return of the disease. In cases in which the cavity alone is affected he proposes amputation of the uterus by laparotomy. He considers it not justifiable to remove the healthy cervix in such cases by vaginal total extirpation. In a case in which extreme narrowness of the vagina rendered total extirpation impracticable he operated in two sittings. At first he removed the diseased cervix by supra-vaginal amputation, and twenty-one days later the remainder by laparotomy. The patient remained free from return for three years after the operation. In all cases of carcinomatous neoplasms on the vaginal portion he recommends supra-vaginal amputation, so long as the vagina is not indurated and the glands and bladder are not affected, in short, so long as the disease is limited to the vaginal portion. Only in cases of total procidentia uteri would he prefer total extirpation as the easier operation. He has performed supra-vaginal amputation in nine cases of carcinoma of the portio, and in two cases the disease returned. One is still recent, so no judgment can be formed as to return of the disease. He operated in the right lateral position; for arresting hæmorrhage he employed the thermo-cautery; large vessels only were ligatured.

Contribution to the Theory of Mixed Infection.—Professor Brieger in the *Zeitschrift für Klin. Med.*, Bd. xi. 3 and 4, reports from Leyden's Klinik three cases of suppuration in various parts of the body in the course of typhoid fever (axilla, mamma, buttock, the thigh, and axillary bubo). It was held that the suppuration was caused by the micro-organism made known by Rosenbach. In one of the cases Brieger found Rosenbach's *streptococcus pyogenes*; in other cases of the kind similar micro-organisms will probably be the cause; in what way the organisms find their way into soil already saturated with infection cannot at present be determined. The already infected body not only facilitates the entrance of bacteria, but every injured part of it offers a favourable soil for their development, as is shown in a case of cholelithiasis observed by the author, in which abscesses developed in various parts of the body. From all the abscesses Rosenbach's *staphylococcus pyogenes aureus* could be cultivated. These possibly might have penetrated from the interior of the intestine, when, in the absence of bile, no obstacles to their development were present.

◆

Scotland.

[FROM OUR OWN CORRESPONDENT.]

University of Edinburgh.—A vacancy has just occurred in the office of Senior Demonstrator of physiology in the University of Edinburgh through an unexpected resignation of Mr. Herbert H. Ashdown. Mr. Ashdown will be greatly missed in the physiological department, where the practical classes under his charge were never better conducted. As an original investigator, Mr. Ashdown had shown much ability. His latest research on absorption from the "Urinary Bladder," has just been published in the *Journal of Anatomy and Physiology.*

St. Andrews University and the Establishment of a Medical School at Dundee.—Report says that both the St. Andrews and Dundee authorities are actively moving in the direction of the early establishment of a completely equipped medical school at Dundee, to be affiliated with the University of St. Andrews. This is a most important announcement in view of the introduction of an Universities (Scotland) Bill. It is rumoured that the two first years of study might be arranged within the present year.

Highland Centenarians.—There has just died at South Uist, a crofter named John Martin, who had reached the age of 104 years. In Beorring, Skye, there likewise died the other day a woman named Campbell, who was upwards of 100 years old, and up till a day or two before her death she was able to walk about. She was the mother of a large family, and in her younger days she had often seen the famous Macorimons, the pipers of the Macleod of Macleod.

The Proposed Glasgow Southern Hospital.—At a meeting of the Glasgow Town Council, held on the 6th inst., a deputation was introduced advocating the claims of the proposed Southern Hospital. Mr. Reny Watson submitted a memorial from the executive committee of the proposed institution. It stated that the memorialists now proposed to proceed with the erection of a portion of the hospital for which the Town Council had granted an eligible site in 1881 in the Queen's Park at a moderate rate of feu duty. The cost of the portion which the memorialists now desired to go on with would be about £20,000, and towards this there had already been obtained, without any general canvass, subscriptions to the extent of about £8,000. The memorial further stated that as the Corporation of Glasgow had already acted cordially and liberally towards the enterprise, it was desired that their co-operation should be invited in getting the approval of Her Majesty for the bestowal of her name upon the institution as a most appropriate commemoration of her jubilee year. Speaking in support of the memorial, Mr. Watson said that as compared with other large cities Glasgow was far behind. In Dublin the proportion of beds in infirmaries supported by voluntary subscription, to the population, was 1 to 157, and in Edinburgh 1 to 400, while in Glasgow it was only 1 to 700. Once established, he felt confident this infirmary would be maintained as had been the others, and he strongly urged its claims, more particularly as the present infirmaries were unable to meet the demands upon them. Mr. ex-Provost Ure also spoke in favour of the proposed institution. We think, however, that such statements in the light of Dr. Erskine's able pamphlet are certainly very surprising. Let other cities be as they may, there is unquestionably too much hospital accommodation in Glasgow, and with the difficulty experienced in keeping up the Royal and the Western Infirmaries, how this new hospital is to be maintained, we fail to see.

Correspondence.

THE ÆTIOLOGY OF PLACENTA PRÆVIA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—May I call attention to the fact that Dr. Braxton Hicks has been no more fortunate than Dr. Fleming in getting the name of the writer on Placenta Prævia in the *American Journal of Obstetrics* for December, 1884, correctly printed, as the author is Dr. Lomer (not Dr. Lownes), assistant to Professor Schroeder, of Berlin.

Dr. Braxton Hicks will also find a very full account of his method in the "Thése d'Agrégation" (accouchements) for 1886, by Dr. A. Auvard, a most able monograph, just published by Octave Doin, 8 Place de l'Odéon, Paris. "De la conduite a tenir dans les cas de placenta prævia," where it is spoken of in the highest terms. Since my paper on placenta prævia was published in your columns I have tried Dr. Braxton Hicks's method in one case, and was much pleased with it, but still I prefer separating the placenta, and dilating with Barnes's bags, as it has given me such good results. I have now treated twenty-seven cases, without a single death, due directly or indirectly to the complication, indeed, all my patients are still alive except one, my twenty-fifth case, which died soon after my attendance ceased, from starvation, the money which was very kindly supplied by her usual medical attendant, Dr. Ridley Dale, to supply food, having been spent by her husband in drink to celebrate her recovery, so, indeed, this may be said to be a death due indirectly to her confinement. I attribute my hitherto good results to my always inducing premature labour as soon as placenta prævia is diagnosed after the seventh month, and remaining with my patient till completion of labour, as though there may not be such necessity for this in a Maternity, where at least the house-surgeon is always on the spot, and prepared for every emergency, it is quite different with my cases, as the hospital to which I am attached, like other provincial infirmaries, does not receive labour cases, so all my cases have been treated in their own homes in Sunderland and neighbouring towns, and in many of them had labour been allowed to come on spontaneously, I have little doubt that the hæmorrhage that would have occurred before a doctor could be obtained would have rendered a very undesirable result.

I am, Sir, yours, &c.,

Holly House, Sunderland, James Murphy.
Dec. 29th, 1886.

◆

DOGMATISTS AND EMPIRICS, ANCIENT AND MODERN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—During the third and second centuries B.C. the medical profession in Alexandria was divided into two rival sections, named respectively the *Dogmatists* and the *Empirics.* Of the former, Herophilus was a distinguished member, and of him, history records that he was an enthusiastic "experimenter," but a very indifferent medical practitioner. Serapion, a pupil of Herophilus, impressed with these characteristics on the part of his teacher, broke away from the *Dogmatists* and became a prominent member of the *Empiric* sect. In the first century A.C. Celsus carefully examined and compared with each other the opinions of these two sects, and with the result as regards himself, that he adopted that of the Empirics, that is, the sect whose knowledge of practical medicine was obtained by means of clinical experience, and by study, as opposed to the Dogmatists, whose knowledge was derived from "experimental research." And it is recorded of Celsus that his analysis of those rival opinions was performed in a candid and judicious manner.

From that time to the present, medicine has been dominated, now by one set of opinions, now by another; each has flourished for its day, then passed away, some into oblivion, others to resuscitate after a long period of degeneracy, and then to undergo, as before, their several stages of growth, maturity, and decay. Thus we read of the various medical sects, called respectively pneumatics, eclectics, methodics, anatomists, clinicists, intro-mathematists, solidists, animists, and so on. With regard to each of these controversy has raged wildly for a time. But fortunately for the true interests of the medical profession, a large section of its members whose sphere has been, and is, the actual treatment of patients, have obtained their "grasp" of their work by means of their clinical experience, and by their gifts for inductive reasoning from that experience.

In the latter quarter of the nineteenth century the medical profession in London includes two opposing sects, corresponding to the *Dogmatists* and *Empirics* cf ancient Alexandria as above described. I endeavour to compare and balance against each other their several statements and opinions, and to draw such conclusions as to my judgment the data thus obtained warrant. Having done so, I adopt the side of the "Empirics," that is, of the "clinicists," for the reason that with them remains the great preponderance of argument and of fact. For so doing, the critic of my *brochure* entitled "New Theory," &c., thinks I am altogether wrong, and emphasises his belief by the use of strong epithets with regard to me. I, on my side, consider that the views taken by him of the claims of the *Dogmatists* of the day is an erroneous view, based upon the study of only one phase of those claims.

This being the case, I would beg to submit to you and to him the following proposal, in the hope that the merits of the large and important question regarding which we so widely differ may be adjudicated on. I do so not because he and I personally differ—for that is relatively of no importance—but in the hope that such a decision on questions regarding which a division of opinion exists throughout the great body of the medical profession may be authoritatively decided on by members of our common profession.

My proposal is that materials which I have collated from *both* sides who have taken part so far in the general controversy to which I allude as "Modern Dogmatism," and embracing nearly, if not quite, every point that has been brought up in the course of that controversy, be submitted to a committee to be composed of my critic, another "Dogmatist" and an "Empiric," or clinicist. I would further propose that after perusal and due analysis of the evidence *pro* and *con* relative to each successive point therein embraced, the committee may send to you direct their decision upon the whole, and that you, if you see fit, shall publish in the *Medical Press and Circular* the purport of the decision they thus arrive at. If that decision be favourable to my view, I win; if unfavourable, I lose confidence in my own power of analysing evidence.

Yours, &c.,

25 Westbourne Square, W. C. A. Gordon.
January, 1887.

◆

FEES TO MEDICAL WITNESSES FOR THE CROWN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—As it falls to the lot of most medical men some time or other during their career, to be summoned as Crown witnesses to assizes, I think the following narrative will be of interest to my professional brethren. I also hope it may be the means of directing attention to the subject, with the view of bringing pressure to bear on the Treasury:—

1. To make general the rule now followed by many judges, of allowing medical witnesses, living twenty or more miles from the assize town, £3 3s. a day and 15s. a night, instead of £2 2s. a day and 10s. a night.

2. To prevent Crown solicitors from arbitrarily sending home a medical witness in the middle of an assizes, thereby upsetting all his arrangements, and depriving him of the fees that up to this latest "Treasury minute," he had as a matter of course.

I received a Crown summons to attend the late Winter Assizes worded as usual, viz., "to attend and give evidence on behalf of the Crown, and herein fail not at your peril, *and to attend from day to day until discharged by the Court.*" A foot note stated that "medical witness are not to attend until the *first day* of the Assizes." Upon receipt of this summons I, in accordance with the 22nd article of the Local Government Board's regulations, communicated with the Chairman of Committee for the district of which I am medical officer, with the view of his providing for the wants of the district. So far so good, but, two days before the Assizes, I met a policeman on the road, who told me that the Crown solicitor had written and desired that the witnesses should be kept at home until further orders, as it was expected that cases from other counties would go on first. However, not being satisfied with this, I, with Dr. ———, medical officer of the next district, who had been treated in exactly the same manner, went to the Assizes the first day (a Thursday), and saw the Crown solicitor, who was indignant at our not obeying his orders. I said that I did not believe that the verbal orders of a policeman could override the Crown summons. The upshot of the interview was, that he told us to come up on the following Monday. What happened? As if to show the utter confusion things were in, Dr. ——— was telegraphed for on the next day. I came up on the Monday, and on the next Saturday was told by the Crown solicitor to go home until further notice. To make a long story short, I actually attended twelve days and was only paid for ten, because, forsooth, the other Crown witnesses in the case had been up only that number of days. To finish the history, at the termination of the case I went before the judge and asked him for an order for the extra guinea a day and 5s. a night, which two other judges had ordered for me at previous assizes. He refused, saying that he would make the order only in the case of persons coming from a distance. Yet I live three miles from the railway station which is 27½ miles from the assize town. I think the thoughtful consideration of these facts will prove the necessity of agitating so as to place medical witnesses above the caprice of a judge or a Crown solicitor.

Another matter to which it may not be out of place to allude to here, is the want of consideration to which professional witnesses are treated in the line of accommodation. Certain seats in the Court House ought to be set apart for them. Resident magistrates practically have this privilege, surely medical men, as a rule, are not their inferiors either socially or intellectually, but perhaps the most uncomfortable part of one's duty at an assizes is waiting to be called before the grand jury. It does not appear too much to ask that a suitable waiting room be provided for this purpose, so as not to have professional men lounging about with the ordinary witnesses on stairs and corridors.

I am, yours, &c.

A.M., M.D., M.C.

THE "JACOB TESTIMONIAL."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I have forwarded to the secretaries £2, my own and Dr. Hobson's contribution to this fund.

As I believe no man has done so much as Dr. Jacob for us dispensary medical officers of Ireland, I should be sorry not to have my name amongst the subscribers.

Only yesterday, Dr. Bolton of this place obtained a decree against the Carlow guardians for £6 6s., and £1 1s. expenses, for acting as my substitute for two weeks while on sick leave. This case would never have been taken up but for Dr. Jacob's energy and advice, and for the influence and support of the Irish Medical Association, before whom he brought it.

I am, Sir, yours, &c.,

E. Campbell Hearne.

Ballickmoyler, co. Carlow.

◆

At the Societies.

PATHOLOGICAL SOCIETY OF LONDON.

The last meeting of the Pathological Society, held on the 4th inst., being the annual general gathering, an election of officers for the ensuing year was held, and the choice of president in the person of Sir James Paget cannot fail to be a subject for congratulation, auguring as it does a further brilliant career of usefulness for an association that has long been powerful for good in the profession. In the retired president, moreover, Dr. J. S. Bristowe, the society has possessed a most able and enthusiastic supporter of its aims and objects, and even the distinguished surgeon who now reigns in his place may well be satisfied, if, under his *regime* an equal amount of progress can be chronicled by-and-bye. Dr. Bristowe has laboured long and successfully to advance the science of pathology, and that his tenure of the principal office of honour in this connection in England is properly appreciated by his fellow pathologists was clearly shown by the emphatic way in which the meeting endorsed the resolution, conveying their thanks to the retiring president.

The business of the evening was opened by Mr. F. S. Eve, who exhibited an interesting specimen of multiple cavernous angioma of the leg. In the same patient from whom this structure was removed, there existed also three calcified enchondromata situated on the digits; and on each end of the tibia exostoses were present, while a sarcomatous tumour sprang from the back of the same bone. The case illustrated the dependence of tumours on defective development, and it was pointed out by Mr. Symonds that a similar case had been recorded by his colleague, Mr. Howse, in the Guy's Reports.

A discussion arose regarding the structure of a tumour next described by Mr. Butlin, which was of a melanotic character, occurring in the breast of a woman aged sixty-four, and removed four times within six years. According to Mr. Butlin, it was of sarcomatous origin, but possessing a distinctly alveolar structure; none of the internal organs appeared to be diseased. Mr. A. A. Bowlby did not consider the tumour to be a result of true melanosis, but, judging from the vascular distribution, regarded it as a sarcoma. Mr. D'Arcy Power also spoke to the structure of the growth, the nature of which Mr. Butlin desired to have decided by the Morbid Growths Committee.

The possibility of recovery from meningitis of tubercular origin was raised by Dr. Carrington, in connection with the history of a remarkably interesting case under his care at Guy's Hospital. The patient was a youth of seventeen, who had been knocked down by a tricycle, and invalided only for a week. Fifteen months later, however, one knee having during this time continued to swell, the other knee also began to suffer, and later psoas abscesses formed. Death eventually ensued, and post-mortem evidences of old tubercular meningitis, as construed by Dr. Carrington, were discovered. Against this conclusion it was suggested by Mr. Shattock that the signs indicated peri-arteritis rather, and by Dr. Bristowe, that the tubercular nodules were not necessarily ancient growths. Dr. Carrington, however, guided by the appearances he saw, and also by his experience of the case during its life, could not accept either of these explanations, and the matter consequently remains practically where it was.

An instructive case of peripheral neuritis in a girl the subject of Raynaud's disease formed the topic of the next communication, read for Dr. Wiglesworth by Dr. Coupland. The patient suffered from chronic Bright's disease, and dementia with epilepsy; X. was twenty-six years old. She died suddenly, in a fit, and post mortem the posterior vesicular column of the cord was found chiefly affected, while in the white substance the neuroglia was somewhat thickened. Fibrous overgrowth was extensively distributed in the nerves, but mostly among the peripheral branches. The discussion naturally turned upon the causation of the condition known as Raynaud's disease, Mr. Bowlby thinking that it depended on disease of the peripheral nerves. Dr. Barlow attributed its occurrence to more widespread changes, as was shown, he thought, by association with it of paroxysmal hæmoglobinuria, amblyopia, and jaundice, which indicated a wider pathology than peripheral neuritis. Drs. Harrington, Sainsbury, and J. A. Ormerod also joined in the discussion, but without adding any observations of importance to those previously made.

A specimen of ruptured aneurism from a syphilitic subject given to alcoholic excesses was shown by Mr. Withers Green, and a number of card specimens were exhibited by various members of the society.

MEDICAL SOCIETY OF LONDON.

Dr. Ralfe read a very erudite paper on the subject of phosphatic diabetes. He pointed out that although no method of ascertaining the quantity of phosphates present had been suggested short of volumetric analysis, yet that such analysis could be conducted without too much difficulty once the apparatus set up. In these days, when the examination of the urine had become a matter of routine, it was desirable to make this examination as thorough as possible.

Mr. A. Pearce Gould read the notes of a very instructive case in which the femoral vein had been accidentally ripped open by a knife in the hands of a cat's meat woman. The hæmorrhage was very profuse, and was not controlled by pressure above or below the site of injury. The wound was carefully enlarged, and a ligature applied above and below, and as the hæmorrhage continued, ligatures were also applied to the internal popliteal and external circumflex veins. The femoral artery was exposed, but was apparently uninjured. For a day or two the patient, an Italian organ-grinder, did well though there were slight shiverings and some elevation of temperature. Then unmistakeable symptoms of septic infection set in, and the artery itself gave way and had to be secured. The patient ultimately succumbed. The wound was carefully cleansed with a solution of perchloride of mercury, but this does not appear to have checked the effects of the poison doubtless communicated by the knife.

Mr. Gould pointed out that wounds of veins were comparatively rare, the companion artery being also generally injured. In that case, however, no injury to the artery had been detected, though it might, of course have been wounded.

Mr. Morgan mentioned a somewhat analogous case as the result of a bullet wound of the sternum, which had occurred at Charing Cross Hospital, the preparation of which was now in the museum of that hospital.

THE VICE-PRESIDENCY OF THE IRISH COLLEGE OF SURGEONS.

Mr. Croly, Senior Surgeon of the City of Dublin Hospital, has issued cards as a candidate for the Vice-Presidency of the College, for which the election will take place on the first Monday in June. Mr. Croly is at present a Councillor of the College, which office he served on a former occasion. He on two previous occasions occupied the position of Examiner in Surgery in the College, and is so well known as an Irish surgeon and writer on all things surgical as to need no introduction from us.

We have already announced the candidature of Mr. Fitzgibbon, who is also Surgeon to the City of Dublin Hospital, and a Councillor of the College.

As the Membership of the K.Q.C.P.I. and the degree of M.A.O. of Universities in the United Kingdom are now registrable at the offices of the three Branch Medical Councils, it is desirable that those holding these diplomas should apply at once to have them registered, so as to appear in the Medical Register for 1887.

Literature.

HART AND BARBOUR'S GYNÆCOLOGY. (*a*)

THE third edition of the well-known Manual of Gynæcology by Drs. Berry Hart and Freeland Barbour has been put in our hands. It is not too much to say that the volume will justly maintain the high reputation which the work has already achieved. In addition to the evident signs of careful revision of the text, an obvious advantage has been gained by the omission of the chapters on extra-uterine gestation, abortion, and retroflexion of the gravid uterus. Such subjects are more logically discussed in a treatise on midwifery. The space rendered available by the deletion has been utilised for the introduction of several new chapters on subjects which have come into greater prominence since the previous editions were issued. These are characterised by the same clearness and definiteness of statement, which distinguishes the work. Occasionally the terseness unfortunately lapses into baldness, but, after all, this is a fault on the side of virtue. The value of the volume as a work of reference has been further enhanced by an elaborate index of gynæcological literature in the leading home and foreign periodicals, while the citations in connection with references in the text have been rendered more complete and exact.

◆

FLINT SOUTH'S CRAFT OF SURGERY. (*b*)

SIR JAMES PAGET explains the object and scope of the late Mr. Flint South's work in a short introduction written in his usual finished style.

The memorials of the "*Craft* of Surgery," have to do more with its business and corporate life than with the progress of surgery as a science, or as an art, and yet many useful lessons and facts of great interest, will be found on studying the result of Mr. South's laborious researches.

The reader will note perhaps with surprise, and certainly with interest, that in the first half of the 15th century, the surgeons and physicians anticipated the conjoint examination of the two colleges in 1885. "He (the reader) may wonder why so good a plan should have lapsed for more than four hundred years, and may find the bad reason for this and many other errors in the maintenance of vested rights, as if they were better than the promotion of knowledge. Or he may wonder that women were licensed to practice surgery in the 14th century and hindered in the 19th; or that in the 16th century licences were granted for the separate practice of specialities; and then as in the study of a development, he may consider whether the abolition of those usages was like the timely cessation of processes that had only an embryonic use."

One good result of the work before us will be to dispel the errors commonly prevalent, even among our profession, of the relations that used to exist between barbers and surgeons. After the Conquest the ecclesiastics were nearly the only persons who taught and practised physic (as well as other sciences), and they found it so lucrative that monasteries became deserted and religious duties neglected. In consequence of this, the Councils of Lateran and Tours issued decrees prohibiting monks from teaching and practising physic. As a natural result, apothecaries and lay surgeons came into existence, and the Jews—who next to the clergy were possessed of the largest share of learning by being in some measure a medium of communication both in literature and science throughout the Western Hemisphere—became the popular physicians. The priests looked with a jealous eye upon the encroachments of both the Jewish physicians and of the lay surgeons, and obtained through their interest at Rome a formal excommunication against all who committed themselves to the care of the former, and by the canon law no Jew might give physic to any Christian. The priests again endeavoured to unite the two branches of medicine and surgery, but Pope Innocent III jealous of such an interruption in the duties of the clergy and looking on the manual part of surgery as derogatory on the plea that the church "abhorret a sanguine," finally debarred them from shedding blood by an ordinance in 1215.

Later on the priests were absolutely forbidden to practise surgery, but wishing however to keep up their hold upon the art they taught the servants who shaved their heads the minor operations in surgery and to work under their direction. "These men qualifying themselves by the instruction of the clergy, assumed the title of barber-surgeons, and became a confraternity or fellowship. The more enlightened of the barber-surgeons again, in the march of knowledge, by attending lectures and practicing dissection, began to spurn such a degrading conjunction, and at last, freeing themselves from the barbers, became a College of Surgeons."

There were at that time surgeons pure and simple, who were neither barbers nor ecclesiastics, but they were very few in number, numbering only twelve in 1513. As Sir James Paget points out the utility of the barber-surgeon may still be observed in several parts of Europe. Thus in Russia many of the Feldshers who are generally educated to be military hospital attendants became barber surgeons in villages and in the poorer parts of towns. The account of the origin of the Barber-Surgeons Guild is of general interest especially to the historian and antiquarian. It shows that guilds were formed not only for the protection of their members, but to strive against the hereditary oligarchy which ruled London; then these guilds ultimately succeeded in converting civic government at least into an elective representation. The barber-surgeons took their place as one of the livery companies of the City of London in 1460.

"Side by side with the barbers, the Guild of Surgeons existed. They were at first merely incorporated as a confraternity, but at a later period they obtained a charter. This guild appears to have been of comparatively recent origin and to have sprung out of an association of the military surgeons who had been trained in the hundred years (1337 to 1444) war with France. It was always a small body, but the members were the *élite* of the surgeons of the time. After an attempted alliance with the physicians, the surgeons amalgamated with the Barber's Company, the two being united by a charter granted in the year 1540 by Henry VIII."

Thus though the real surgeons had previously held themselves apart as a distinct body, and though they had for a time combined with the physicians (1421), they formed an official junction—hardly an union as there was no fusion of the two callings—with the barber-surgeons in 1540. The surgeons were not allowed to practise shaving and the barber-surgeons were not allowed to do more than draw teeth.

"In 1745, after a union of more than 200 years, the surgeons severed themselves from the barbers, and established a new body called the Surgeons' Company, founded on the exact lines of the pre-existing united corporation. By a foolish blunder in 1796, the charter was forfeited, and failing to obtain an Act of Parliament for the reconstruction of their Company, the surgeons were incorporated by a charter of George III in the opening year of the present century as the Royal College of Surgeons in London."

The thanks of the profession at large are due to Mrs. South for so kindly placing her deceased husband's manuscripts in Mr. D'Arcy Power's hands, and to Mr. Power himself for the skilful way in which he has arranged them.

The plates which adorn the work are exceeding well executed and altogether the volume has been tastefully produced.

Subscriber," &c. Much confusion will be spared by attenion to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

A. R. C. (Aldershot).—Your incredulity neither shocks nor surprises us, and as to your reference to Dickens' defence of what is called "Spontaneous Combustion" in man, the theory through which he gets rid of the troublesome victim of his interminable lawsuit in Bleak House, we doubt its scientific accuracy and even physical possibility. As to Monsignore Virtue's statement that "not one day passes in England without men being carried off by excess in liquor, and who literally die drunk, and that some have been seen whose whole interior frame had got so burnt by the intemperate use of spirituous liquors, *that at last on passing near a fire they caught fire themselves and were reduced to ashes*," we believe that it admits of a very similar but, if possible, a more negative qualification. There is, in short, no evidence to show that such an occurrence as he contemplates ever occurred in this or in any other country, but that thousands die of excess of liquor annually in these islands is certain, and the drink bill exceeds, we believe, some £130,000,000 per year in this country alone.

DR. ALFRED D. (Cannes).—Paper on "Treatment of Phthisis by Gaseous Enemata" received.

A POET'S FARE AND PHYSIOLOGY.

"WHEN the physiology of poets has been studied, we shall perhaps know, says Prof. Dowden ("The Life of Shelley, vol. i., p. 86), why Wordsworth and Shelley were water-drinkers, why Keats loved an exquisite claret, why Southey soothed himself to sleep with a tumbler of domestic currant rum, why Byron, in his later days, craved the fierier and fiercer stimulants. 'Poet's food' he (Shelley) has told us 'is love and fame,' but his friend Peacock preferred 'three mutton chops well peppered,' and the same friend intimates that his vegetarian diet did not agree with him. It made him weak and nervous, and it exaggerated the sensitiveness of his imagination." And it would be interesting to know how far, if at all, the growing taste of the day for this species of food affects the physique or the imagination of its votaries.

DR. A. D. (Alpes Maritimes).—We do not keep files of the journal referred to, and doubt if you will get the odd numbers required in this country, as there is no agency. We would advise you to write direct to the editor or publishers at the New York office.

MR. H. WILSON.—We have made inquiries and found the amount collected by the "Carol Singers" in Hammersmith, "ostensibly for a hospital," has been duly disbursed, twenty guineas having been received by the authorities of the West London Hospital. You were a little hasty in your suspicions.

DR. WISE (Maloja, Suisse).—Enclosure received with thanks.

DR. R. D. S. (Fulham).—The matter is under consideration.

DR. G. E. HERMAN.—With pleasure.

MR. A. S. MANDERS (Melbourne).—If you will send us a reminder later on we shall be happy to accede to your request.

A PUZZLED STUDENT.—A little perplexing we grant. "Ala" is supposed by some authorities to be of Arabic origin, a corruption of "al" in the sense of a prefix, meaning *the*. When applied to anatomy it is generally considered as a corruption of the Latin *axilla*; in botany it is applied to the side petals of papilionaceous flowers.

HEALTH OFFICER.—You are not quite correct in your figures, and your contention will be weakened in consequence unless you bring forward indisputable facts before the authoritities. The following are the figures at the six metropolitan fever hospitals:—

	Gross cost per day.	Patient's cost per head.
Hospital Ships..........	20s. 10½d.	2s. 0½d.
South Eastern Hospital..	18s. 1½d.	1s. 1½d.
Stockwell „	14s. 8d.	0s. 11½d.
Western „	10s. 9½d.	1s. 3½d.
North-Western „	8s. 0d.	1s. 0d.
Eastern „	6s. 1d.	1s. 0½d.

MILITARY SURGEON.—But you forget that, in case of need, the President of the United States can call out seven millions of educated Republican militiamen, more than double those of the hosts of Germany and Russia combined. The cost of the armaments of the United States is £9,000,000 per annum, that of Great Britain £29,000,000. But whereas the monarchy spends only £6,600,000 on public education, the Republic lavishes £18,600,000 on that object!

◆

Meetings of the Societies.

WEDNESDAY, JANUARY 12TH.

HUNTERIAN SOCIETY.—At 8 p.m., The President, Cases of Lead Poisoning terminating rapidly with Cerebral Symptoms.—Dr. Fox, The Nature of Asthma.—Dr. Turner, Actinomycosis of the Liver.—Mr. Symonds, Further History of a case of Intestinal Obstruction.

EPIDEMIOLOGICAL SOCIETY OF LONDON.—At 8 p.m., Mr. Edward F. Willoughby, Preventive Inoculations.

OBSTETRICAL SOCIETY OF LONDON.—At 8 p.m., Specimens will be shown by Dr. Amand Routh and others.—Dr. Pedley, Midwifery among the Burmese.—Dr. Herman, Stricture of the Female Urethra.—Dr. Gibbons, Case of Unilateral Galactorrhœa.

BRITISH GYNÆCOLOGICAL SOCIETY.—At 8.30 p.m., Annual Meeting. Presidential Address.

FRIDAY, JANUARY 14TH.

CLINICAL SOCIETY OF LONDON.—At 8.30 p.m., Annual General Meeting for the Election of Officers and Council. Dr. Samuel West, Right Hemiplegia with Aphasia occurring during a Paroxysm of Whooping-Cough, with slight rigidity, subsequently passing into a condition of Athetosis.—Mr. Mayo Robson (Leeds), (1) A Method of Treating Thyroid Cysts; (2) A Suggested Method of Operating on a Uniform Principle in the Treatment of Imperforate Anus.—Living Specimens: Dr. Radcliffe Crocker, A Case of Athetosis after Hemiplegia.—Dr. Stephen Mackenzie, Living Embryo Filariæ Sanguinis Hominis from a case of Chyluria.

Vacancies.

Worcester General Infirmary.—House-Surgeon. Salary £100 per annum, with board and residence. Applications, with testimonials, &c., to the Secretary, not later than Monday, Feb. 7th.

Flintshire Dispensary.—House-Surgeon Salary £100 per annum, with furnished house, &c. Applications, with testimonials, to the Secretary, on or before Jan. 25th.

Lampeter Union.- Medical Officer. Salary £30 per annum. Applications, with testimonials, &c., to the Clerk, on or before Jan. 27th.

Chorley Dispensary.—House Surgeon. Salary £130 per annum, with house. Applications, with testimonials, &c., to the Hon. Sec., before Jan. 20th.

Bedford General Infirmary and Fever Hospital.—Resident Surgeon. Salary £100 per annum, with board, &c. Applications and testimonials to the Secretary, not later than Feb. 3rd.

Scarboro' Hospital and Dispensary.—House-Surgeon. Salary £80 per annum, with board and lodgings. Applications and testimonials to the Medical Staff, on or before Jan. 25th.

Appointments

CLARKE, A. B., L.R.C.S.Ed., L.S.A., Medical Officer for the Shebbear District of the Torrington Union, Devon.

COLLENETTE, F. de B., M.R.C.S., L.R.C.P.Lond., Medical Officer of Health for the Wolstanton Rural Sanitary District.

FENWICK, C., L.R.C.S., L.R.C.P.Ed., Medical Officer for the Dunsford District of the Exeter Union.

GRAHAM, W., M.D. Roy. Univ. Irel., L.R.C.S.Ed., Resident Medical Superintendent of Armagh District Lunatic Asylum.

HARDY, A. E., M.R.C.S., L.S.A., Senior House-Surgeon to Charing Cross Hospital.

HAWKINS, F., M.B., Physician to the North London Hospital for Consumption and Diseases of the Chest.

HOCKEN, J. P., L.S.A., Resident Obstetrical Officer to Charing Cross Hospital.

HUDSMITH, P., L.K.Q.C.P.I., Medical Officer of Health for the St. Anne-on-the-Sea Urban Sanitary District.

LAKIN, C., L.F.P.S.Glas., L.R.C.P.Ed., Medical Officer for the First District of the Leicester Union.

LITTLEWOOD, J. O., M.R.C.S., L.R.C.P.Lond., Medical Officer for the Borough of Walsall.

LUCY, R. H., M.B., C.M.Edin., M.R.C.S., House-Surgeon to the South Devon and East Cornwall Hospital.

MACDONALD, P. W., M.D., C.M.Aber., Medical Superintendent to the Dorset County Asylums.

MAKINS, G. H., F.R.C.S., Assistant Surgeon to St. Thomas's Hospital, has been appointed Demonstrator of Anatomy to that Institution.

NELHAM, A. E., M.R.C.S., L.S.A., Junior House-Surgeon to Charing Cross Hospital.

NORRIS, E. J., M.R.C.S., L.R.C.P., L.S.A., Senior House-Physician to Charing Cross Hospital.

OLIVER, W. P., L.S.A., Junior House-Physician to Charing Cross Hospital.

Births.

HILLS.—On Dec. 27th, at Carlton House, Battersea Park, S.W., the wife of A. Phillips Hills, M.R.C.S.E., F.S.Sc., of a daughter.

SILK.—On Jan. 1st, at 9 Pemberton Road, Holloway, the wife of Frederic Silk, M.D.Lond., of a son.

Deaths.

ANDREWS.—On Jan. 3rd, at New Barnet, Charles Andrews, M.D., of Hammersmith Road, W., aged 59.

BARON.—On Dec. 27th, at Woodland Terrace, Plymouth, Edward George Baron, M.R.C.S., late of Ulceby, Lincolnshire.

BROWNE.—On Dec. 20th, at Rhyl, North Wales, H. D. B. Browne, M.B., House-Surgeon to the Flintshire Dispensary, aged 23.

CURME.—On Jan. 2nd, at Dorchester, George Curme, M.R.C.S., L.S.A., in his 80th year.

HOLMES.—On Dec. 31st, at San Remo, Surgeon-Major A. P. Holmes, 1st Sikhs Infantry, aged 51.

JACKSON.—On Dec. 23rd, William Jackson, M.D., late of Kingsland Road, aged 75.

LINTON.—On Dec. 29th, at Bristol, Cornelius C. Linton, Inspector General of Hospital, late Indian Medical Service, aged 83.

MACKENZIE.—On Dec. 18th, at Eileanach, Inverness, N.B., John MacKenzie, M.D., aged 83.

MOORE.—On Jan. 1st, at Much Hadham, Herts, Francis Moore, M.D., aged 80.

RANGER.—On Dec. 27th, at Bexley Heath, Kent, Frederick Ranger, M.R.C.S., late of Cranbrook, Kent, aged 67.

REE.—On Jan. 4th, at Addiscombe, Surrey, Frederick George Ree, L.R.C.P.Lond., M.R.C.S., second son of Dr. Ree, late of Fulham.

SELLERS.—On Dec. 28th, at John Street, Rochdale, William Burdett Sellers, M.R.C.S., L.S.A., aged 67.

SMART.—On Dec. 26th, suddenly, at Queen's Crescent, Glasgow, Robert Smart, M.D.

Original Communications.

SUBDIAPHRAGMATIC ECHINOCOCCI AND THEIR TREATMENT.

By Dr. LEOPOLD LANDAU,

Docent der Gynekologie, University of Berlin.

THE author read this interesting paper before the Berlin Medical Society on November 1st, embracing four cases in which operation for the removal of echinococci had been performed, and illustrated by three of the patients on whom the operation had been successful.

The first case was that of a women, æt. 36, who had borne 11 children. From 30 years of age she noticed a swelling in the epigastrium, and another in the right hypochondriac region. The tumour was very large and uneven on the surface, and caused distressing dyspnœa. The heart was displaced to the left. The upper border of the swelling reached to the fourth rib. Downwards in the axiliary line it reached to the crest of the ilium. Aspiration showed that the tumour was an echinococcus cyst of the liver. Operation May 27th, 1886. The incision was made in the linea alba, three finger breadths above the umbilicus, and continued cautiously to the end of the ensiform cartilage. As the cyst was high up, close to the diaphragm, the liver was drawn down and anteverted in order to bring the desired spot within reach. Then, as in a former case, two sutures were passed through the abdominal wall, peritoneum, and liver parenchyma, and the upper and lower angles of the wound, which were held untied by assistants and drawn tight. The liver was then incised in the most prominent part, and hundreds of daughter echinococcus cysts spouted out. The finger was then passed into the parent cyst and the remainder cleared out. In addition to the cysts about half a litre of clear fluid escaped from the cyst. The cut surfaces of the liver were now united by vertical sutures to the opening in the abdominal wall, and after washing out the cyst with 1·5000 solution of sublimate and the insertion of three rubber drainage tubes the wound was closed by Listerian dressings. Recovery was uninterrupted, the cavity not requiring any further syringing. On August the 15th the wound was completely closed. The patient became pregnant for the thirteenth time on November 1st.

The second case was that of a nullipara, æt. 37. The cyst was situated high up, and interfered much with respiration (42 per minute). Percussion over left lung normal. Over the right dulness began in front of the fourth rib, and behind at the middle of the scapula. Right thorax and intercostal spaces much bulged out. Downwards dulness extended to the navel. Exploratory puncture of the liver through the soft abdominal walls gave no result, but by deep puncture between the eighth and ninth ribs in the axillary region a clear fluid was obtained. It was difficult to decide whether the cyst was in the kidney (anterior surface) or the liver (posterior surface). Operation November 8th, 1885. The abdominal incision was made from the axillary line parallel to the fibres of the external oblique, about 16 cm. long, and about 8 cm. above the thick margin of the liver. In order to gain space the incision was forked at each end. The other structures were then divided regardless of the direction of their fibres, and the liver dragged as far as possible to the left and still more retroverted. It was then stitched to the abdominal wall, as the operator was satisfied that the opening into the cyst could be made from the extreme end of the incision. The liver was then incised a little above the twelfth rib in the anterior axillary line, with a pointed scalpel, the point being directed sharply upwards. Whether the cyst had perforated the diaphragm could not be ascertained. The cyst reached as high as the third rib, and the finger could not reach to get them away. They were dislodged as much as possible by means of a long blunt-ended sound, and three thick drainage tubes were inserted. The liver and the abdominal wall were then united for a distance of 6 cm. The course after operation was for six days very unfavourable. Lung complications, fever, and urticaria rendered prognosis doubtful. On the fifth day œdema of the lungs supervened, which was overcome, however, by subcutaneous injection of camphor, and brandy. From the seventh day the symptoms became more favourable. On December 8th the drainage tubes which had remained in from the operation were shortened. Profuse secretion of bile was then noticed, lasting two days. Recovery from this date was uninterrupted. In five months after the operation the patient had gained thirty-six pounds in weight.

The third case was also that of an unmarried nulliparous woman, æt. 30, with an elastic tumour on the right side reaching from the axillary region almost to the umbilicus. Exploratory puncture showed that it was an echinococcus cyst, but whether of the liver or right kidney could not be decided. Operation April 24th. The incision was made from the anterior axillary line, close to the ribs, and parallel with the fibres of the external oblique down to the tumour. This was found to be the right lobe of the liver. It was forcibly pushed to the left and attached to the abdominal walls by sutures passing through at the upper and lower angles of the wound, not tied, but drawn tight, thus completely shutting off the peritoneal cavity. The cyst lying backwards was now incised, when the mother cyst, only a few daughter cysts, and about one litre of fluid spurted out. The subsequent steps of the operation were as in the previous cases, and the patient recovered rapidly and completely. The patient had also an echinococcus cyst on the left thigh, which was enucleated at the same time.

The fourth case was that of a man, æt. 34, who had suffered for ten years. The following measurements were taken :—Xyphoid process to symphysis 46 cm. (18 in.); from umbilicus to symphysis, 19 cm. (7½in); from umbilicus to xyphoid, 26 cm. (10 in.); girth at umbilicus 86 cm. (33¾ in.); 5 cm. below umbilicus 83 cm. (32½ in.); 10 cm. below umbilicus, 65 cm. (25 in.); at the 12th rib, 88 cm. (34½ in.); thorax over nipples, 79 cm. (31 in.). Percussion sound absolutely dull over the whole of the right side. There were three distinct groups of tumours that did not communicate with each other. The case was so serious that operation could not be delayed. Operation June 5th, 1886 (in Dr. Güterbock's Klinik). The incision beginning at the convexity of the left ribs was carried a distance of about 20 cm. parallel to the fibres of the external oblique down to the cyst, which was previously attached by four sutures to the abdominal wall. About six litres of cysts of the most varied size escaped without external pressure. The hand could then be passed into the cyst which ran for a distance of about 40 cm. (15¾ in.) diagonally upwards behind the posterior surface of the liver towards the diaphragm. This was forced up so high that the forearm, passed into the cyst almost up to the elbow, could not reach the farthest extremity. Notwithstanding the escape of such a large quantity of cysts the liver did not fall back into its normal position. By this peculiar behaviour of the liver, assisted by the fixed bony thorax and the aspiration of the lungs, a large cavity of greater size than a man's head remained after clearing out the echinococci. The upper boundary was formed of the whole of the diaphragm with the exception of the two lateral borders. The cyst itself extended over the posterior surface of the right, and a portion of the left lobe of the liver, reaching close to the neighbourhood of the spleen. From this portion the echinococcus cysts were not removed, as they were firmly retained by aspiration, and it was not possible to reach them with the hand. After destroying and removing as many of the cysts as was possible, three drainage tubes, each the thickness of the thumb, and 40 cm. (13¾ in.) long, were inserted behind the liver. A second opening was also made in the posterior wall, through which another drainage tube was passed. The left side now showed two marked prominences, under the convexity of the left ribs and in the left iliac fossa. Examination showed that these were two separate and distinct mother cysts. The one under the ribs was attacked first. It was pressed strongly against the abdominal wall and cut down upon. It was evident that it was situated in the omentum. Enucleation was then attempted, but as this did not succeed on account of the intimate union of the base with the intestine, and especially with the transverse colon, the walls were resected as far as possible, and the remainder of the connective tissue capsule attached to the abdominal wall, and a drainage tube inserted. The third was reached with difficulty as intestine lay over it. It was situated apparently in the parietal peritoneum of the ilium, or in the mesocolon of the flexura sigmoidea. After cutting through the abdominal wall, taking care of the intestine, it was pressed against the abdominal opening, attached to this by two sutures, cut into, and drained. The operation altogether lasted one and three-quarter hours. The whole course of recovery was free from fever. From the day of operation, for three and a half months, the secretion of bile was so profuse that the fæces remained without any admixture of it. They were clay-cloured until July 7th. Even then the escape of bile from the large opening did not cease till August 15th. The cavity contracted so slowly that in the beginning of August several drainage tubes, 35 cm. long, were required to prevent the accumulation of bile in the cavity. Closure was so slow that the question was repeatedly ventilated whether resection of some rib would not be necessary in order to effect it. Notwithstanding the fact that not a drop of bile escaped through the ductus choledochus the slow recovery was not interfered with. On September 15th the drainage tubes were finally removed, followed by rapid closure of the cavity.

(The report of the cases is followed in the original by a careful consideration of the diagnosis, vital and clinical phenomena, and various methods of treatment employed for the eradication of the parasites, for the reproduction of which we have not space at our disposal.)

◆

A MAN named Mullett died last week at Bolton from hydrophobia. He was bitten by a dog in October last, and though the wound was immediately sucked by his son, and subsequently cauterised, symptoms showed themselves on Wednesday last, and he died in great agony.

NOTES FROM THE HISTORY OF MEDICINE AND OF MEDICAL OPINION

FROM THE EARLIEST TIMES.

By Surgeon-General C. A. GORDON, M.D., C.B.,
Hon. Physician to H M. the Queen.

(Continued from p. 26.)

MEDICINE had now (thirteenth century) become a general branch of education at most of the Universities of Europe. That of Salerno, already mentioned, was the first of those establishments after the destruction of the Roman Empire. Then followed in succession those of Montpellier, Bologna, Vienna, Paris, Padua, Pavia, Milan, Rome, and Naples. In all these, however, the doctrines of Hippocrates and Galen were adhered to with slavish servility. [As are, at the present day, doctrines and theories which happen to be, from accidental circumstances, brought temporarily into prominence.] The Italian surgeons held opposite opinions with regard to the correct method of treating wounds, and both sects appealed on the subject to the writings of Galen. Of these the one found in these writings, that "moisture and relaxation of tissues are more natural than dryness and tension," the members of that sect accordingly treated their wounds with moist applications. Another sect considered that "dryness approaches more nearly to the natural than moisture," the employment of desiccating remedies was the proper mode of treatment. (Meryon, p. 77.) [And even at the present day differences of opinion not dissimilar from that just expressed prevails among surgeons.]

In one respect a very remarkable similarity existed between the opinions entertained in the thirteenth century and that which characterises advanced science in the latter part of the nineteenth. In the former there was a prevailing belief that an intimate relation existed between the human body and the planets, and that therefore, medicines should be administered in relation to planetary influence (Meryon, p. 188). In the latter the belief was expressed by a distinguished savant that "one chain of causation connects the nebulous original of suns and planetary systems with the protoplasmic foundation of life and organism." (Med. Congress, 1881.)

Not far from the time of Gilbertus Anglicanus, in the fourteenth century, lived John of Gaddesden. He was Professor of Medicine in the University of Oxford about the year 1320. In his method of practice he appears to have ministered to the luxurious appetites and refined tastes of his patients, "so as to play them into health rather than disgust their palates with nauseous potions, or hurt their delicacy by the operation of rough medicines." He tempted the wealthy and the delicate by his luscious viands; he pampered the ladies by devising new perfumes, divine cosmetics, and exquisite oils. And yet John's reputation stood so high that he was specially sent for to attend the son of Edward the Second when the prince had an attack of small-pox. On that occasion his treatment consisted in wrapping his patient in scarlet cloth, and draping his bed and room with the same colour, "by which means he so effectually cured the prince that not a single spot remained to detract from the beauty of his visage." Such was the fashionable physician of that day; such the means by which he obtained his high reputation. We learn also that he "conquered epileptic attacks with his Anoydine necklaces, and cured paralysis of the tongue with aqua vitæ. But, notwithstanding the characteristics just mentioned, he made some observations that are of importance to medicine. Thus he noticed the circumstance previously alluded to by Paulus Aegnita and Avicenna, that paralysis of the limbs occasionally follows attacks of Colica pictonum; also that, as recorded by the Chinese, a repetition of an attack of small-pox sometimes occurs. Unfortunately the "Rosa Anglica," by which name the chief work of this author and fashionable physician was known, has the reputation of containing certain remarks of a nature scarcely in accord with modern ideas of taste and morals.

About the year 1363 Guido de Chauliac published his "Magna Chirurgica." That work, partly relating to the labours of different authors, but chiefly the result of practical experience of its author, reduced the art of surgery to a system. In surgery he revived the use of the trephine, and invented a forceps for taking up wounded arteries. He gave the case of a man who recovered after the removal of a considerable portion of cerebrum or anterior part of the brain; a circumstance the more remarkable, as it appears to be the first case of the kind recorded in the annals of Brain surgery. "In Galen also mention is only made of the brain being wounded, but not of any part of it coming out." (Freind, vol. ii, p. 321) Chauliac discussed the subject of strangulated hernia, the Cæsarian section, amputation; and in relation to the latter, "disapproves of the practice of giving narcotics to allay pain adopted by Theodoric and others." Adverting to the plague which in the year 1353 nearly depopulated the whole world, he ascribed the disease to "the influence of the three great planets, Saturn, Jupiter, and Mars entering into conjunction into the sign of Aquarius on the 24th of March, 1345." He observed that two forms of that disease prevailed, and he gave descriptions of each. It was about this period that the use of gunpowder in war began; he accordingly discussed the method of treating gunshot wounds, and it is evident from his own statements on the subject that, although the applications used by him were rough, yet he effected some remarkable cures.

He describes the various methods followed in his day by the five classes of practitioners in the treatment of wounds, whom he enumerates. The first of these applied poultices to all wounds and abscesses; the second used wine only; the third treated wounds with ointments and soft plaisters; the fourth sect, mainly Germans, who attended the wars, used promiscuously charms, potions, oil, and wool; and the fifth, women and ignorant people, had recourse only to saints. All these, he said, continued to tread in the same track, and to follow one another like cranes. In many other places we met with several things which the more modern practitioners have given out as their own inventions. (Freind, vol. ii, pp. 321-2.)

John Arden or Arderne lived in the latter part of the fourteenth century. In his time the operation for fistula was performed "by ligature," that is, drawing the thread by way of sewing, in this manner representing what in modern times became the *écraseur*. It was considered that this method was a great improvement over the actual cautery for the same operation as recommended by Albucasis. His description of venereal disease, including ulceration or excoriation, with heat of the urine, or *Brœnning*, was all taken from the Arabians ("Freind," vol. ii, p. 355). As in France the revival of surgery was ascribed to Guy de Chauliac, so in England it has been credited to Arderne. It is said of him that he alwaya took the precaution to make a bargain with his patients before he entered upon the case, and advises physicians to stipulate for as much as they can get, and to obtain security for the payment of the sum as soon as the cure is complete (surely a code of professional ethics that has nothing in its favour, but every consideration against it).

About the same period *Petrus de* Apono advocated the medicinal employment of mercurial fumes, on the ground that "though hurtful to the nerves, they expel and kill all other poisons."

In the fourteenth century the outbreak of "The Black Death" in England was, by the physicians of the period, attributed to "an unknown change or corruption in the air," which might be caused by the putrefaction of locusts that had perished in the sea, and were thrown up, combined with astral and telluric influences (in other words the theory of zymotic origin was assigned to the outbreak). During the same period, as well as in the fifteenth century, all disordered states of the body were supposed to result from the *veins*. One set of medical men, namely, the advocates of "derivation" believed that Nature was apt to set up local and active congestions, towards which the noxious humours flowed; the revulsionists, on the other hand, considered that local disease originated in a kind of metastasis of humours (Meryon p. 229). According to Louis Mercado, at that time, all diseases were a subtraction or minus without any material cause (p. 341). Mizauld and Nostradamus sought for the causes of epidemic diseases, and for their remedies in the relative position of the planets (p. 395).

With reference to the general condition of medicine in the fourteenth century, we learn that it had to surrender its pretension to the more practical sciences of natural history and natural philosophy; physicians endeavoured to make it a practical art, but in the absence of correct data it was thus degraded into a coarse empiricism (Meryon, p. 217). [Let those who make a study of such subjects say how far the remarks quoted are applicable to more modern times.] Europe teemed with physico-spiritual advisers (p. 191). While one set of physicians attributed the plague, which at that period prevailed, to the planets as already observed, another set attributed the same disease to "a putrid corruption of the blood," and recommended "a purification of air and a nutritious diet as the best protection against it" (p. 211). Isolation and quarantine in the case of plague-stricken places were at this time instituted (p. 214).

In this century the sect of Rosicrucians, *i.e.*, *ros crux*, dew cross, arose (1302) in Germany. They proposed to hold, and to teach the same doctrines as did the ancient philosophers of Egypt; the Chaldean Magi of Persia, and the gymnosophists of India. In 1614 they received their distinctive title (p. 462).

As teaching of medicine declined in Asia, it became transferred to Europe, where, for a considerable period it remained chiefly in the hands of the clergy. As the art of printing developed, so did the study of professional subjects extend. But for a long period even subsequent to that date the system followed, alike by clerical and medical practitioners was that of the Arabians, namely, pure empiricism, that is, the empiricism of experience, although undoubtedly, not unfrequently mixed up with what is at the present day better known by the term, otherwise charlatanism and systematic deception. As already noticed also, advantage was taken of the prevailing credulity of the times by men whose reputation stood high. Certain diseases were attributed to the presence of "poison" in the system, and in them the treatment was directed to "drawing out" that poison. In principle, at least, personal hygiene was indicated; so was attention to the nature and quality of food, and of the best methods—according to the opinions of the day—of preparing it. With regard to the treatment of fevers one need only turn over the collections of authors on that subject to be quickly satisfied, how little that age added to what had previously been said with regard to it.

In the early part of the fifteenth century, namely, in 1418, Valescus, or Belascou, a native of Portugal, wrote a work entitled "Philonium," which contained many observations in medicine and surgery. Instead of treating attacks of pleurisy by means of "warm" medicines, such as hyssop and origanum, after the manner of the ancients, he employed refrigerants in that disease. In fact, the name of this author comes down to us in reference to the circumstance, rare at that period, that instead of blindly following authority, he thought for himself.

He proposed the extirpation of cancerous tumours by means of preparations containing arsenic; at the same time, adverting to the use externally of arsenical preparations for Tinea, he alludes to the fact that sudden death had in certain cases followed therefrom;

The name of Savanarola stands pre-eminent in reference to all mineral waters in Italy, on the properties of which, at the same time, he wrote a treatise.

It was in this century that scarlet fever for the first time made its appearance in Italy. Previous to this time the operation of lithotomy continued to be performed by itinerant practitioners. In 1460, however, Germain Colot having witnessed their method of operating practised the operation on the dead body, and then upon a condemned criminal, and so successfully that the latter made a rapid recovery, and was rewarded with a free pardon and a pension.

◆

SOME EXTRA-PROFESSIONAL EXPERIENCES.

By Brigade-Surgeon W. CURRAN,
Army Medical Department (Retired.

[Contiued from page 8.)

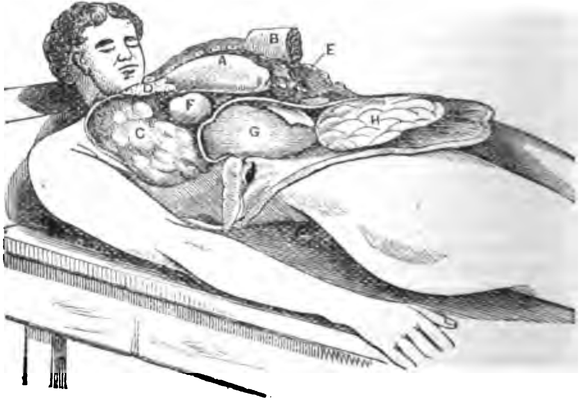
Case III.—A Curious Congenital Displacement.

The following case occurred under my care at Pembroke Dock, South Wales, and it is so striking or suggestive in itself, as to call for inclusion in these reminiscences. I had not before seen, neither have I since heard, of anything at all like it, and the testimony it bears to the efforts of Nature to adapt herself to the requirements of a faulty mechanism, or a primary abnormality, is very strong. It almost, in short, embodies a paradox, by showing that, contrary to the usual and accepted teaching of physiology, digestion may be carried on for years, not only with impunity, but with more or less efficiency, through the medium of a stomach that had been, so to speak, turned upside down upon itself, and had this strange malposition been recognised during life there is no saying but that experiments might have been carried on through it, as well 'fore as 'aft, that would have thrown those of Dr. Beaumont into the shade. However that may be, it never occurred to me, or to any one else, that this poor lad was the subject of such a displacement as I am now going to describe, and therein lies, as I think, the peculiar import or significance of this unique lesion.

George A., æt. 19, recruit, was admitted to hospital as above, on the 5th of June, with a small boil on the back of his neck, from which he had suffered for some two or three days previously. This was treated in the usual way, and he was doing well up to the forenoon of Saturday, June the 9th, when he first complained to the orderly of the ward of headache, thirst, and a sense of tightness and throbbing about the forehead and temples. Having subsequently exhibited some signs of mental disturbance or general excitement, I was asked to see him, and finding him very hot, confused, and irritable, I ordered him an emetic. He could not, however, be induced to vomit, and he afterwards complained to the ward master (in deprecation, I presume, of his further efforts in that direction) that he never in his life remembered being sick. His mother confirmed this part of his statement, and added that he was always ailing and delicate. She further intimated that he used to suffer from uneasiness or oppression about the chest after food, and she gave us to understand that palpitation and dyspnœa invariably following rapid motion or other unusual exertion or excitement on his part. How under such circumstances he got into the service I do not know, but there he was, and truth is in this, as in so many other instances, sometimes stranger than fiction.

Having had to perform the usual Saturday inspection, I visited him again on my return from the huts hard by, and was informed that he had been very freely purged. Whatever he took by the mouth appeared, in short, to pass through him very soon after it was swallowed, and indeed almost unchanged; but there was still nothing about him to excite alarm, and the weather was at this time close and sultry. Having prescribed some lemonade and also a cooling spirituous lotion for his forehead, I left him under the impression that he would soon be himself again. Not so, however, for I had scarcely settled to a book in my room than my attendance was again pressingly requested, as the patient was said to be struggling convulsively in a fit, and on my arrival in the ward I was surprised to find that he had ceased to breathe, and was otherwise to all appearance quite dead. I endeavoured to resuscitate him by the then fashionable "Ready Method," but failed of course, and I then opened a vein in his arm. This procedure was also a failure, and, after a short pause, I ordered his removal to the dead-house.

On section, twenty-six hours after death, and as the symptoms immediately preceding death pointed to irritation of the brain, the cavity of that substance was examined, with the following results. A quantity of dark fluid blood—estimated at two or three drachms—was found pressing on the dura mater, about midway between the frontal sinuses and the parietal suture, and this did not appear to result from any rupture or laceration of a large vessel. It appeared rather to have oozed out of the longitudinal sinus. On percussing the walls of the chest previously to their removal I was surprised to find that this tapping elicited a clear, ringing sound, like that of a pneumothorax. Unable to account for this resonance at the time, or unwilling to acknowledge, even to myself, so grave an error of diagnosis, I hesitated for a moment, and then opening the chest, was surprised, or rather, gratified, at finding that after all my diagnosis or treatment was not at fault. The stomach was, in short, completely displaced upwards through an opening that existed in the left tendon of the diaphragm, and occupied such a position in front of the left lung as must, after food or when otherwise distended, have gravely interfered with the functions of that organ, and had, indeed, so compressed this lung against the spine as to reduce its weight to six ounces, and deprive it of almost all sponginess or elasticity. The right lung weighed, however, twenty-two ounces, and must have done double duty for many years back. Finally, this erratic viscus had quite filled up the left cavity of this lad's chest, and, for the rest, are not the appearances disclosed well represented by this engraving. (*a*)



A. Stomach displaced upwards.
B. Portion of omentum withdrawn from under the stomach and placed on a piece of sponge.
C. Right lung.
D. Atrophied left lung.
E. Diaphragm.
F. The heart.
G. The liver.
H. Folds of intestine uncovered by omentum.

(*a*) The sketch from which this engraving was made was taken by the late Dr. R. Wolseley, who was then, like myself, an assistant surgeon at this place. I believe that, from what has since transpired on the point, he was killed by a fall from his horse at Meerut on or about the very day or hour on which this note was written. As he and I often rode to hounds together, while we contested at least one steeplechase in the pigskin, I can testify to his more than average horsemanship.

The heart was also displaced downwards and to the right, but there was no appearance of any recent rent, laceration, or rupture of the diaphragm, and the edges of the part of it that surrounded this protrusion were rounded, indurated, and callous. This membrane itself was held *in situ* by a thin band of ligamentous tissue that stretched loosely from the right tendon to the wall of the chest, and that allowed a free communication between this cavity and the abdomen. The left kidney occupied the place usually assigned to the spleen, which latter, adhering slightly to the subjacent pleura was found lying within the walls of the thorax. So were also several coils of the large and small intestines, some of which were, doubtless, drawn up by the efforts at vomiting that preceded death, but other portions were as clearly due to the unnatural position of the pylorus —which was closely jammed in under the left clavicle— and the conclusion I arrived at in respect of this displacement at the time, and to which I may say, I still adhere, was that it was the result of a congenital deficiency of this muscle, rather than of any recent rupture or spasm of its fibres.

On discussing the matter with my then two *confrères*, one of them, who had served for many years in New Zealand, assured me that he had seen a somewhat similar case in that colony in the person of a banker who "after retiring early to bed the previous evening with an over-loaded stomach, was suddenly seized with faintness and vomiting. When I saw him, said Mr. Bacot, the symptoms were obscure and puzzling, his skin was cold and clammy, his pulse rapid and small, his countenance was fearfully anxious, and the features were drawn and haggard. The intellect was however, clear, and there was little or no pain, tympanitis or distension in or over the abdomen. There were, on the other hand, hiccough, subsultus, and unavailing spasmodic attempts at vomiting, and my informant came to the conclusion that Mr. M. was suffering from the effects of a strangulated bowel or of an intussusception. He continued to sink in spite of all our efforts to the contrary, and on opening the chest, in presence of several local practitioners, there appeared (continues my friend), what we all mistook for an uncommonly distended pericardium, an unusually large tympanitic and bulging bladder-like mass, which allowed on puncture a very free escape of gas. This settled the question, and led to our recognising this membranous mass, as the stomach displaced upwards in front of the heart, through a recent rupture of the diaphragm," and other ruptures of *this kind* must, doubtless, be within the cognisance of many of my readers.

As to the comparative pathology of this condition, the consideration of it scarcely comes within the scope of these experiences, and it is, moreover, more a question for veterinarians and physiologists than for a mere outsider like myself. All the same I have while rewriting this account of the case, looked into the papers of Montgomery and Vrolick in Todd's Cyclopædia, but they do not, so far as I can see, throw any light on this lesion, or on its consequences, and so we had better address ourselves to that feature of it with which we are most concerned or conversant ourselves. Encased as this boy's stomach was in a comparatively immovable cavity, and beyond the reach of either abdominal or diaphragmatic agency, it is no matter for surprise that he could not be induced to vomit. The wonder would lie on the other side did he do so, and this—his resistance to our stimulation—may serve to throw some light on the once much debated question of the vomitory or non-vomitory powers of the horse.

Gerard regarded the somewhat analogous position of this animal's stomach, that is to say, near the spine, and separated from the floor of the abdomen by the intestines, as an insuperable obstacle to such healthy compression of its walls, as would enable it to reject its contents. Youatt, M. Colin and several others ascribed this weakness or non-capacity (?) to the mechanical arrangement or interlacement of its (the stomach's) œsophageal fibres with those of its cardiac sphincter, and the question is still, I believe, *sub judice*. The late Mr. Gamgee, on the other hand, regarded "the fact that therapeutics, as applied to the horse exclude emetics, as settling the point, and he held that the fact, that the great majority of experimenters have agreed on the inoperativeness of emetic substances, even when injected into the veins of that animal" as conclusive against the assumption of a merely mechanical obstruction. He refers the rarity of vomition in the horse to his total insusceptibility to emetic action, and probable physical indifference to ordinary nervous excitation, and how far this case bears upon the question of vomition in the horse, or whether it throws any light at all on the mechanism of emesis in our own or other species is for you, gentle reader, to determine.

◆

Therapeutic Notes.

By GEORGE FOY, F.R.C.S.,

Surgeon to the Whitworth Hospital, Drumcondra; and formerly Lecturer on Anatomy and Forensic Medicine in the Carmichael School of Medicine.

SULPHATE OF BERBERIN.

The alkaloid berberin has recently come again into notice, principally through the writings of Schatz, of Rostock, who has recommended Hydrastis canadensis, of which berberin is the active principle, very highly as a reliable agent in checking or restraining uterine hæmorrhages under various conditions. Fellner, of Vienna, has stated that it is an ecbolic, but this is denied by Schatz, who maintains that its action is limited to the blood vessels.

The sulphate of berberin has recently been submitted to independent investigation by Dr. Schurinow, of St. Petersburgh, in which the following conclusions have been reached.

1. Small doses of berberin slow the action of the heart for a short time, after which acceleration follows from paralysis of the peripheral portion of the vagus.
2. Arterial pressure is diminished from its action on the vasor-motor nerve apparatus.
3. The respiratory centres are curtailed by small doses and paralysed by large ones.
4. Sensibility to pain is diminished by lessening the conductivity of the sensory nerves.
5. Vomiting and peristaltic action of the bowels are produced by it.
6. It is eliminated by the kidneys only.
7. It has no ecbolic action.

TREATMENT OF PERITYPHLITIS.

In a case of perityphlitis, occurring in a young man, æt. 22, caused by eating an immoderate number of oysters—(*Medical and Surgical Reporter*)—(a not very probable cause in this country), Dr. Hutchinson, in whose care the case was, successfully treated him with large doses of opium, inunctions of oleate of mercury to the gums, until they were slightly touched. Nourishing diet, but of a kind that will not distend the bowels, milk, &c., the bowels to be relieved by enema. And he further recommends the patient to be detained in hospital for some days after convalescence.

INTRA-PERITONEAL INJECTION IN HÆMORRHAGE.

Dr. Rutgers, of Rotterdam, publishes in the *Weekblad van het Niederlandsch Tijdschrift voor Geneeskunde*, a case of dangerous post-partum hæmorrhage, which was attended by a midwife, and not seen by himself until four hours after delivery, hæmorrhage still continuing. Injections of ergotine and ether were given, and the patient swallowed some port wine. A saline solution 6 grammes of chloride of sodium and 0·3 grammes of the hydrate of sodium to the litre of water was prepared. After vainly attempting its injection into the brachial veins, Dr. Rutgers injected half a litre into the peritoneal cavity with the best results. From his success in this case he recommends a trial of the same plan in cholera.

PHARYNGEAL NASAL DOUCHING.

In a paper contributed to the *Southern Medical Record*, Dr. A. G. Hobbs thus refers to the use of the nasal douche for catarrhal conditions of the mucous membrane:—"Should the posterior nasal douche be used? Never! While it can do more good (if effectually used, and not one person in ten can ever learn to effectually use one) than the anterior douche, it may do a great deal more harm by throwing the fluid into the Eustachian tube, and causing middle ear inflammation.

RESULTS OF PASTEUR'S INOCULATIONS.

In a recent communication to the Academy of Science, M. Pasteur stated that 2,490 persons had been treated by his method for rabies. These patients were from almost every civilised country, the different nationalities being represented as follows:—

England	80	Russia	191
Austro-Hungary	52	India	2
Germany	9	United States	18
Belgium	57	Roumania	22
Spain	107	Turkey	7

Of the French and Algerian patients ten died. Two deaths being attributed to tardy arrival, the death of Russian patients being uncertain. M. Pasteur's faith in the treatment is still unshaken, but to the majority of readers the necessity he feels for a more perfect and severe treatment than he adopted earlier is hardly proof of the efficacy of the treatment.

Clinical Records.

CHARING CROSS HOSPITAL.

Cancer of Rectum—Lumbar Colotomy.

Under the care of Mr. J. Astley Bloxam, F.R.C.S.

Charles J., 73, surgical instrument maker, was admitted on October 6th, he said he first noticed a difficulty in passing his motions about eighteen months ago, and this gradually got worse. Six months ago he had inflammation of the testicles, and since that time he has been quite unable to retain his motions, but this inability only supervened gradually. His motions are liquid and small in quantity, but necessitate a good deal of straining. He has a motion about every hour. Latterly, his appetite has fallen off considerably. His occupation necessitates a good deal of sitting. His wife and children died of consumption. Patient complains of smarting pains just before going to stool and during its passage. There is troublesome flatulence with some abdominal tenderness. He has periods of calm followed by a recurrence of the smarting in left groin, and to some extent in the right groin. Patient was ordered five grains of pil. saponis co. at bed time, and although it did not procure sleep the frequency of the attacks of pain was diminished.

9th.—Patient complains of the constant running from the anus accompanied by a smarting pain. He sleeps badly, but takes his food better, and the abdominal tenderness has disappeared.

19th.—Patient has much improved under opiates. He has no pain in the bowels except after meals, and the running from the anus is less troublesome. He was placed on a water-bed to-day. The patient being anæsthetised Mr. Bloxam performed the operation of lumbar colotomy, the direction of the incision being two inches behind a line drawn vertically upwards from a point midway between the anterior and posterior iliac spines on the left side. No great difficulty was experienced in finding and securing the gut. The edges of the wound were then brought together as far as necessary by means of sutures, and an antiseptic dressing applied.

20th.—Patient complains of a good deal of pain in right hip and down right thigh, especially on moving. He was placed on his back, and the water-bed removed. The urine had to be drawn off with a catheter, in consequence of his being unable to pass it.

21st.—Two sutures were removed to-day, and the wound dressed antiseptically.

23rd.—Patient complains of severe scalding pain along the course of the urethra. His urine dribbles away, and any attempt to check it causes him great pain. The wound is going on well, a small quantity of fæcal matter collects in the immediate neighbourhood. Temperature, 98·4° F. Pulse strong, and not compressible. He is on milk, beef-tea and port wine.

24th.—Since yesterday patient has passed one motion by the rectum, and three by the artificial anus, but the quantity evacuated each time was small.

25th.—Patient has been having linseed meal poultices to the left side, and this morning, on removing the poultice a fair quantity of solid fæces came away from the artificial anus. The third suture was taken out, and the wound is now healed up. The pain in the urethra is less, a catheter was tied in last night. Patient sleeps pretty well. Patient left the hospital on the 13th November much improved in general health.

CASES OF SKIN ERUPTIONS AND SYPHILIS TREATED WITH HORSFORD'S ACID PHOSPHATE.

By Mr. James Startin,

Late Honorary Surgeon and Lecturer, St. John's Hospital for Skin Diseases, London; Honorary Consulting Surgeon to the Sheffield Public Hospital for Skin Diseases.

It appears to me that the "acid phosphate" originally prescribed by Professor Horsford, of Cambridge, U.S.A., is not so well known in this country as its merits deserve. A glance at the formula will however readily convince one of its value in suitable cases. Each fluid drachm gives on analysis 51-2 grains of free phosphoric acid, and nearly four grains of phosphate of lime, magnesia, iron and potash. The following are a few brief notes of some of the cases in which I have prescribed it with complete success.

Mr. G., æt. 69, consulted me November, 1885, for eczema on the arms, legs, palms of the hands, and trunk. The patient complained of much debility and nervous exhaustion, and he was a man who had led a very busy business life with much worry. In December, 1885, I prescribed Horsford's acid tonic with much good effect, as in February, 1886, I heard that he was quite well.

Mrs. S., æt. 46, consulted me in December, 1885, for psoriasis all over the body more or less, especially on the legs and arms. In January, 1886, I prescribed a teaspoonful of the acid tonic three times a day with marked good effect. Patient had been much exhausted by continuous nursing on an invalid mother.

Mr. C., æt. 64, consulted me in September, 1885, with one of the worst attacks of late syphilis I ever saw. After he had been relieved from the distressing symptoms, and ulcerations, I prescribed the acid tonic for epileptiform fits from which he suffered, with excellent results.

Mr. McJ., æt. 63, consulted me in November, 1885, for lichen ruber, which was accompanied with intolerable itching. He was a nervous irritable man. I prescribed the acid tonic with the effect that in December he presented himself quite convalescent.

The Mortality of Foreign Cities.—The annual death-rates per 1,000 in the principal foreign cities, according to the last weekly returns communicated to the Registrar-General, are as follow:—Calcutta 40, Bombay 22, Madras 39, Paris 23, Geneva 21, Brussels 20, Amsterdam 24, Rotterdam 20, The Hague 23, Copenhagen 18, Stockholm 20, Christiania 29, St. Petersburg 29, Berlin 21, Hamburg 36, Dresden 19, Breslau 31, Munich 28, Vienna 24, Prague 32, Buda-Pesth 31, Rome 28, Turin 22, Venice 25, Cairo 43, Alexandria 34, New York 29, Brooklyn 24, Philadelphia 23, and Baltimore 21.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, JANUARY 14TH, 1887.

Thomas Bryant, Esq., F.R.C.S., President, in the Chair.

A CASE OF RIGHT HEMIPLEGIA WITH APHASIA IN A CHILD.

Dr. Samuel West read the notes of a case of right hemiplegia with aphasia occurring during a paroxysm of whooping-cough, with slight rigidity, subsequently passing into a condition of athetosis. He attributed the paralysis to hæmorrhage, possibly into one of the central ganglia, but of course this could only be surmise.

Dr. Radcliffe Crocker said that he had had a case with a very similar history to that of Dr. West's. A girl, æt. 10, was brought to the hospital in November last complaining of inability to use the right hand. On examination there was a condition of athetosis and spasm, just as Dr. West had described. On making forced extension of the hand the fingers began to close up, then the wrist was bent in pronation. On making inquiry as to the history, it appeared that twelve months ago the child had three right-sided fits in twelve hours, the last being followed by paralysis and aphonia. The child was unable to talk for three weeks, and to walk for three months. The athetosis came on about three weeks after the onset of the paralysis. As to cause, he found that the child had a mitral obstructive and regurgitant murmur, and therefore the inference was that it was a case of embolism. Her general condition did not appear to have made any progress during the last three months.

Dr. Broadbent said that he thought the lesion in Dr. West's case was more likely to be located in the cortex than in the central ganglia. It was of course difficult to localise a cortical lesion which had followed so accurately the motor area.

Dr. West, in reply to Dr. Broadbent's remarks, said that he did not attempt to localise the injury, but only suggested the possibility of the central ganglia being involved.

Mr. Mayo Robson (Leeds) read a paper on

A METHOD OF TREATING THYROID CYSTS,

in which he advocated antiseptic incision and stitching the edge of the cyst to the skin, draining for a short time under an antiseptic dressing, and then packing with zinc lotion and lint. He read notes of two cases thus treated, the first in a girl, æt. 22, who had a cyst the size of a Tangerine orange over the trachea, which occasionally produced dyspnœa; the second in a girl, æt. 24, in whom the right lobe of the thyroid was forming one large cyst. In both the above treatment was perfectly successful, and produced no constitutional or local disturbance. When seen some time afterwards there was very little trace of scar, and no tumour in either case. He quoted from several standard surgical works to prove that the usual operations for thyroid cysts, such as injection, seton, &c., are either dangerous or unsatisfactory, and thought that the advantages of this method were its simplicity, safety, and certainty.

Mr. Bryant asked Mr. Robson whether, if the cyst had proved multilocular, he would have broken down the divisions.

Mr. Christopher Heath said that Mr. Robson had not spoken of any difficulty with the hæmorrhage, which, in his experience, was apt to be profuse from the interior of the cyst when emptied. For that reason the use of perchloride of iron was probably introduced. He had employed the system several times with success.

Mr. Clutton said that in his experience, hæmorrhage from the interior of the sac was apt to be very profuse. It, however, stopped on plugging, but high fever had succeeded the operation until he employed iodoform gauze for the packing. The fever was then much less marked. He advocated the removal of the cyst wall. One disadvantage of plugging was that the sinus was apt to persist for a very long time, in one case three years.

Mr. Gant said that his experience had led him to make up his mind as to what he would *not* do rather than what he would do. He would never tamper with the cyst walls. He inquired whether, in removing the colloid material with the spoon, the cyst walls were much interfered with.

Dr. Stephen Mackenzie, alluding to his microscopical examination of the cyst walls, said that they contained an abundant supply of thin-walled blood-vessels, very liable to give rise to hæmorrhage, and he inferred therefrom that perchloride of iron was peculiarly indicated.

Mr. Thos. Bryant said the salient point in Mr. Robson's paper was the proposal to stitch the cyst walls to the skin. He hardly thought this was required in the majority of cases. He remembered two cases; one of simple tapping in which a good deal of bleeding took place, and on pressure being applied it became very tense. It all went away, however, when a free incision was made and the cavity packed. In the other case he at once made the incision, and no trouble was experienced with the hæmorrhage. He mentioned that in one case in which he was injecting a mixture of tincture of iron and iodine, the sac suddenly filled with blood and pulsated in a way which caused him considerable alarm. Ice was applied, and after a period of anxiety matters subsided.

Mr. Robson, in reply, said that in both cases the cyst was simple. Had it been multilocular he would have broken down the partitions in order to remove all the contents. The advantage of stitching the sac wall to the skin was that it shut off the cellular tissue of the neck from the danger of infiltration. As to Mr. Clutton's suggestion to excise the part of the gland affected, the difficulty in cutting away the thyroid was to know where to stop. He had done it twice, and both times with imminent risk to the patient, once from asphyxia and once from hæmorrhage. In scraping the walls he employed just enough force to set up sufficient inflammation to secure obliteration of the cavity.

Mr. Mayo Robson (Leeds), read a paper on

A SUGGESTED METHOD OF OPERATING ON AN UNIFORM PRINCIPLE IN THE TREATMENT OF IMPERFORATE ANUS, WITH EXAMPLE.

and read extracts from several authors to prove that the recognised treatment of cases where the bowel is not soon reached is to perform either Littre's operation or colotomy, although the mortality of the operation, judging by published statistics, is extremely heavy, *e.g.*, Mr. Guersant having operated in this manner twelve times without saving a patient. He advocated an incision from the central point of the perinæum to the coccyx, and then a careful dissection, until either the bowel is reached or the peritoneum is opened, when the upper end of the rectum or the sigmoid flexure of the colon can be brought down and sutured to the skin in the anal region. He described a case in a child one day old, on whom, in March 1866, he had performed this operation with a very good result, the child recovering without a bad symptom, either local or general, and when seen last the patient had what appeared to be a normal anus, through which it had a motion about once a day. He considered the operation ought not to be very difficult if a catheter was passed into the bladder and a good horizontal light was available, that it should not be very dangerous either from shock, peritonitis, inflammation, or hæmorrhage, and that the result if successful was infinitely preferable to that of Littre or a colotomy.

Mr. Godlee said that the escape of meconium into the peritoneum did not set up the same irritation as ordinary fæcal matter.

Mr. Harrison Cripps criticised the statistics brought forward at the end of the paper. He had collected about a hundred cases, in many of which Littre's operation had been performed with success. He had had five successful cases out of sixteen. The results of operations when there was no sign of an anus were much more favourable than when some trace could be seen, as the malformation was often more serious in the latter case. He preferred Verneuil's operation of resection of the coccyx without opening the peritoneum.

Mr. Robson, in reply, said that there was an advantage to stitch the mucous membrane to the skin, if only to prevent extravasation of the areolar tissue.

LIVING SPECIMENS.

Dr. Radcliffe Crocker showed a case of hemiplegia followed by athetosis in a child.

Dr. Stephen Mackenzie, chyluria with living specimens of the *filaria sanguinis hominis* under the microscope.

Dr. Angel Money, a case of hemiplegia with spasm in a syphilitic child.

◆

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Meeting held Dec. 18th, 1886.

The President, Dr. Cleaver, in the Chair.

FIBROMA PASSED FROM UTERUS OF A WOMAN, ÆT. 79.

The patient had been under Mr. Baldwin's care, who showed the specimen. Hæmorrhage set in about 1 p.m. the day of seizure; at 4 p.m. the mass shown was passed. All bleeding ceased three hours after it came away. The lump was about as large as a medium sized kidney.

TUMOUR OF THE PANCREAS.

This specimen was shown by Dr. Dyson, who gave brief notes of the case. The patient, a man, æt. 49, by occupation a metal shearer, was admitted into hospital in October, 1886. There was no history of syphilis, gout, or rheumatism in the case. He was married, and had three healthy children. Two years before his last illness, he had been under treatment for pleural effusion on the left side of the chest, for which he was tapped. At that time he presented a peculiar colour very suggestive of Addison's disease. Pain felt down the left side, but not much attention was paid to it. In August I noticed a swelling on the same side. When admitted, he had occasional attacks of very severe pain, with long intervals of freedom from pain. In consultation, after admission, malignant disease was diagnosed. He was in the ward three weeks before he had pain. Felt weak and was losing flesh. Was upon the ordinary diet. At the end of three weeks, pain commenced and continued. The tumour felt in making palpation was really the left lobe of the liver pushed up by the swelling, a cancerous mass in and about the head of the pancreas. The liver was involved. Opium was the chief treatment, and the only treatment which gave relief.

Dr. Dyson believes that the disease commenced in the hylus of the liver, spreading thence to the pancreas, and subsequently to the substance of the liver.

The President asked if there had been any return of the pleural effusion in the left chest?

Dr. Dyson, in reply, said that the pleura had healed by first intention, and that there had not been the slightest return. The tapping had been done on the old system of using trochar and canula under the protection of the carbolic spray.

ON SOME CLINICAL FEATURES OF GRAVES' DISEASE.

Mr. Snell read this paper based on cases coming under his observation. Referring to those cases in which the eyes symptoms were the first to appear, he related particulars of a young woman, in whom the other cardinal symptoms had recently come on. Dr. Dyson, under whose care she now was, introduced her. Another instance was in a woman (introduced), æt. 45, who had Stellway's and Graafe's symptoms, with little (if any) exophthalmos of the eye; small enlarged thyroid unnoticed by patient, and an absence of other symptoms. The left eye was normal. Two monocular cases, besides the one just mentioned, were related, and particulars were given of two instances of suppuration of both corneæ. One, a young woman, æt. 23, was only seen when the corneæ were both seriously affected, and the other, a woman, æt. 40, had both corneæ destroyed when first observed. The question as to the occurrence of Graafe's (loss of coordinated movement of eyelid and globe on looking down) and Stellway's (widening of the palpebral affections) syris independently of the usual train of symptoms, associated under the name of exophthalmic goitre was discussed; the case of a young lady was mentioned, in which in the right eye Stellway's and Graafe's symptoms were both present; no exophthalmia; the other eye was normal; there was an absence of other symptoms; she greatly benefited under treatment. An interesting case was that of a miner, æt. 36, introduced before the Society, with well-marked miner's nystagmus. He had in both eyes also well-marked Stellway's and Graafe's syris. There was no enlarged thyroid or other symptoms of Graves' disease. He seemed to possess some control over the lid phenomena. The pathology of the disease was alluded to, and support given from the cases related to a central lesion theory (Sattler, Fitzgerald).

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 19, 1887.

SUDDEN CHANGES OF TEMPERATURE.

Experience leads us to anticipate certain definite results in the production of disease from marked and sudden variations in temperature. If a north wind sends down the thermometer from 70° to 40° in the course of a day it would not be unreasonable to anticipate an increase in the number of cases of disease of the respiratory organs, rheumatism, &c. The more abrupt the fall the greater will be the effect. Yet with a knowledge of these facts our civilised existence is one continual series of exposure to such changes—changes greater in extent and more sudden than any which occur from natural causes. Instead of a day, the result of leaving a warm room for the streets, may be to affront a difference in temperature of 40° or more, and even within the limits of the same house it is possible to pass, metaphorically speaking, from Greenland's icy mountains to India's coral strand. Of course it will be urged that certain precautions are taken with the view of obviating the risks attending such abrupt changes of temperature, but it will be found on inquiry that they are as a rule quite illusory. Who dreams of putting on an overcoat on going to the closet or fetching any object from another and unwarmed room? On leaving the house, it is true, persons possessed of average prudence take the trouble to put on an extra coat or shawl. By so doing they do protect the *outside* of the body, but they leave unprotected the naked surface of the lungs, a delicate and easily irritated organ, very inadequately provided with means of self defence. Even nature's resources, whereby the equilibrium of heat is maintained, are apt to break down when one inspiration is at 70° and the next at 30°. Nature as a rule does not allow of an abrupt reversing of the gear; her movements are pendulum-like, and adjust themselves, accurately it may be, but slowly, to the vicissitudes of life. In a natural state of existence, which may be assumed to be a savage one, such changes are impossible, or at least improbable, and hence, as we advance in civilisation, so the bad results of an artificial condition of existence become apparent.

Another danger to which our habits of living expose us is that which accrues from *local* disparity of temperature, when, for instance, to use the same simile, our bodies are in India and our feet and legs in Greenland. Here the mechanism is somewhat different, but the result is at least as detrimental. Beginning at the inflamed eye which is caught by looking through keyholes, we get to the neuralgic affections which may attack any part of the body exposed to the action of a draught. Although the cause may be local, the effect is by no means necessarily so; indeed, in a large proportion of cases the result of such localised exposure is to give rise to constitutional ailments, it may be, of the most serious character.

The bad effects of rapid changes of temperature are by no means confined to transition from heat to cold. Very often, indeed, the converse change, from cold to heat is the starting point of a series of complaints which cold alone had failed to induce. This is a matter of common experience in armies on the march in winter. Entrance into a warm room from an outside temperature below freezing point is not uncommonly followed by a sensation of suffocation and malaise, which takes some little time to wear off.

Much can be done by care and attention to ward off part of the harm which might otherwise accrue from the causes alluded to. Inside the house, the warmth should be more equably distributed so as to avoid undue change of temperature on traversing corridors or passages; this involves structural arrangements which are not within the reach of everybody, but excellent results follow even the employment of a stove in the hall. Outside, not only should additional clothing be resorted to, but no air should be permitted to reach the lungs except after having been warmed by passing through the nose —a little contrivance by which nature remedies, within certain limits, alterations in the temperature of the respired air. For this reason singing in the streets on cold nights, and even talking, is undesirable. The most robust are amenable to these influences, to some, if not to the same extent as the more delicate, and cannot brave them with impunity. In cities, especially where fog and cold go together, the maxim should be to keep the mouth shut and the ears open.

SMALL-POX AND RAGS.

THE study of the modes in which disease is propagated offers one of the most attractive paths open for inquiry in the field of preventive medicine; nor is it altogether a misfortune that the nature of the problems it involves is such that a good deal of speculative investigation must necessarily be indulged in by those who pursue it. That the study is difficult from the multiplication of details that surround it, that it is attended by complications often most confusing in their relations, and that the results aimed at are not rarely of the utmost importance, not only in a sanitarian sense, but also socially, is a fact to the recognition of which a great part of the present position attained by it is due; and it is to be hoped that the future progress of this particular line of thought may be in no wise slower, but even still more satisfactory than that which has marked the steady growth of opinion bearing on measures of prevention in the past.

Among the diseases more particularly referred to in this connection are several that have claimed a severe penalty in suffering and death, as the price of that ignorance regarding their dissemination which existed until the labours of patient and skilled investigators had traced their origin to the source, and the histories of which provide some of the most fascinating pages in the record of modern advances in medicine. Thus the details of the discovery of the etiology of malignant pustule or "woolsorters' disease," of cholera, of several of the specific fevers, and above all, of small-pox, familiar as they now are to professional readers, will never fail to call forth a feeling of pride in the achievements which led up to them. As a consequence of the labour which has been expended in elucidating problems of this description, we have been enabled not only to modify the effects produced by the poison severally concerned, but even also to *prevent* in vast numbers of instances, the injury which would arise from its presence, and that, by attacking the virus and destroying its power for evil by obliterating its nidus. In the case of small-pox this is essentially true; and we are led to present mention of the fact because of an interesting discussion which took place on Thursday last at a Local Government Board inquiry held at Ivybridge, near Plymouth, respecting a recent outbreak of small-pox in that locality. The town of Ivybridge is the seat of several paper manufactories, and the epidemic forming the subject of inquiry appears to have originated in the introduction of infected rags for manufacturing purposes. There can, of course, be no hesitation in affirming that when once it has been proved that such a method of introduction is prevalent, the first duty of those entrusted with the task of preserving *salus populi* is to insist on the adoption of measures efficient to that end; and even those personally interested in the maintenance of the industry, that is, the mill-owners, seem to admit this *suprema lex*. But, unfortunately, when they learn the conditions necessary to ensure the protection of their *employés* against the influence of infective germs possibly present in imported rags, the *auri sacra fames* rules stronger than pure humanitarianism, and we are informed that the injury to the rags caused by their saturation with superheated steam, or by other processes designed to promote destruction of the germ elements, would conduce to losses regarded from the trading point of view, and naturally held to be of the utmost importance by traders. The provision of a hospital for the isolation of stricken workpeople was another point entered on at the conference in question, and it seems almost incredible that, though Ivybridge has witnessed three outbreaks of small-pox within as many years, yet no step has been taken in this direction, and further, that nothing definite has even now been settled. The inquiry was presided over by Dr. Parsons on behalf of the Government, and it need not be doubted but that an inspector of his known ability and promptitude will urge on the importance of decisive action in the interests of the large number of people locally affected, and also in furtherance of protection for the national health.

In America the disinfection of rags at once on their being landed is largely carried out by the injection of steam, or of disinfecting substances, performed with specially designed apparatus, the result of long-continued experiment and comparison. We have formerly dwelt on this subject, and have insisted on its importance from a preventive point of view; and now that it has once again arisen an opportunity should be taken of arriving at a definite and general decision to carry out a universal system of disinfection of all rags, &c., imported for manufacturing purposes.

◆

"THE LITTLE FOXES."

Since the days of Solomon the vintage has been threatened, and ofttimes ruined, by "the little foxes that destroy the grapes." No fence is close enough for the exclusion of these "little foxes." Somewhere or other the lanky-bodied managed to pull through the hedge-row, and many a promising bunch of newly-forming grapes met an untimely end, and the vintage lost much of the fruit that would, if saved, have contributed to make it remarkable for its excellence.

What can be done for the extermination of these "little foxes;" social pests that destroy much fruit of promise. Foxes so small, so audacious, and so cunning that ere you can draw attention to their presence they have escaped. Who can tell how much work of promise has been killed by the slighting sneer, or what ardour has been cooled by the disparaging remark. To notice social sins and to prevent the depredations of these thievish little foxes would not be within our province had we not observed with alarm their frequency in our medical societies, and often felt aggrieved to notice the quiet but humiliating sneer that has met the early attempt of some young author to place his ideas and facts before a medical meeting. Unpractised in the art of gaining the ear of his judges by a little preliminary flattery judiciously incorporated into his discourse, he places his observations and deductions before the meeting, and judging from the deference with which papers, devoid of scientific or medical interest, have been received on previous occasions, he naïvely hopes that his, which with much zeal, hard work, and care he has brought forward, will meet with some honest scrutiny. Who can depict his suffering when he finds his paper has called forth no response except the quiet smile that damps his enthusiasm, freezes his hopes, and effectually deters him from ever again offering the fruit of his labours to the withering indifference of his brethren—brethren only in name!

In Solomon's days the "little foxes" confined their mischief to destroying the grapes; in ours the evil has advanced, and the foxes by judicious approval, foster, weeds that occupy the vineyards, choking the vigorous young fruit-bearing plants, and producing at the *vendange* instead of a generous wine, which gladdens the heart, and stimulates to great actions, a wishy-washy swill that produces nothing but wind. The praise in soft murmurs or the hand-clapping that greets him who substitutes a French or German opinion for an honest native observation, pains all who love Medicine for herself, and who do not use her as a prostitute to make money, or as courtiers have done their wives, to get titles.

In one case a man loving his profession has been discouraged. The inelegance of his style and his want of familiarity with foreign literature are quoted as damning sins; while his careful observation and accurate deductions are passed over unnoticed. In the other case the many quotations, the constant reiteration of foreign names, Slavonic, French, German, &c., by one whose whole, or, at any rate, whose principal, merit rests on an ability to write in an agreeable manner, elicits signs of evident approbation. He has merely chosen a plain broad road, without attempting to cut his way through difficulties, all can follow him, his pace is theirs, his path the beaten track.

The pettiest skipper that from Genoa sailed the Mediterranean had less difficulty with his crew than had Columbus, as he day by day stared westward in hope of seeing land. Columbus had thought out his course, had resolution, was determined to win; but did not the "little foxes" nibble at him? Did not the microcephali with sneers, and gibes, and flouts seek to prevent him carrying out his great and self-imposed task—the calling into existence of a New World. How petty to-day appears the intriguing and the manœuvring of the crowned heads of Europe beside this determined sailor's work! How stood this poor Genoese in his coarse clothes by the side of lace-clad nobles? He stood fixed, resolved, God inspired, with an unquenchable determination to do or die. So in Medicine, the honest, though less refined, observation will live—live as a fact useful to all future workers, waiting for the time when one born with prophetic instinct will clothe the dry bones of careful observation with poetic prose, and make them ever-living thoughts, whilst the elegantly clad medley of quotations must die as of the earth earthy, and in time be brushed from the world of thought into oblivion.

◆

Jubilee hospitals promise well, or ill, as one looks at it; in any case, there will be plenty of them. Southend now proposes to commemorate the Queen's Jubilee by the erection of a hospital. The cost is estimated at £2,500, and the annual expenditure at £250. (?) A committee has been appointed to carry out the scheme, and about £500 has been subscribed.

Notes on Current Topics.

The Latest Phase of the Laparotomy Epidemic.

THE following important letter relating to the Liverpool Hospital for Women, from Dr. Thomas Keith, of Edinburgh, appeared in the *Liverpool Daily Post* of Monday, the 17th inst.:—

"SIR,—In your paper of Jan 11th, which has just been sent to me, Dr. Imlach makes the momentous (the word was 'monstrous' in the original) statement that I am entirely in accord with him on the question now in dispute at the Liverpool Hospital for Women. So utterly does my practice differ, that during the last seven years, of a great number of cases submitted to me, and including all operations done by my son, I have only felt justified in advising performance of this operation in not more than half the number that were operated on the Shaw Street Hospital in the course of a single year. I have also had brought under my notice for the first time the printed report of the committee submitted to the governors and subscribers of the hospital. At page 4 it is stated that my opinion on this matter was sought last year by the committee. I never received any communication from them. Had my opinion been asked, however, it would have been to this effect, that at their hospital it seemed to me that there was an undue haste, amounting almost to recklessness, in operating, and that the death-rate of one in every twelve women following an operation for a complaint that, of itself, is rarely dangerous to life, was an excessive mortality, and *far more than sufficient to banish the operation from surgery altogether.*—(Signed) THOMAS KEITH, Edinburgh."

The Executive Committee of the General Medical Council.

A MEDICAL contemporary says that the Executive Committee of the General Medical Council, which met last Friday had before it, among other matters, the mode in which diplomas or certificates in sanitary science are to be registered, and questions connected with the registration of foreign and colonial practitioners, and the employment of unqualified assistants. The proposal under discussion had no reference to unqualified assistants employed in the ordinary way, but to cases of gross misconduct in the employment of so-called unqualified assistants, who are in reality merely covered by a registered practitioner. The question whether the Council have the legal power to order the expenditure of the large sums of money which would be necessary if the proposed visitation of medical schools were carried out, was also considered.

The Association of General Practitioners.

A MEETING of the Council of the Association of General Practitioners is announced to take place at Exeter Hall on Wednesday, Jan. 19, at 5.30 p.m. Mr. Wheelhouse, President, will take the chair, and resolutions will be proposed approving of the proposal for securing to the general practitioners of England the means of obtaining the M.D. in London by reasonable and adequate examinations, but asking for a Royal Commission of inquiry into the constitution of the Colleges of Physicians and Surgeons before granting any charter for the extension of their powers and privileges, more particularly with the view of securing a voice in their councils for the general practitioners, who compose 95 per cent. of the profession. A resolution deprecating the exclusion of the Apothecaries' Society from the conjoined examining board will also be proposed.

Pate de Foie Gras.

COINCIDENT with agricultural depression, it has been suggested that a welcome addition to the income of farmers might be managed if geese were treated in this country in such wise as to render us independent of Perigord and Strasburg in the matters of this dainty dish. The price at which it is sold is certainly high enough to allow of a very decent margin of profit in spite of the cost of the *truffes* which generally enter into its composition. This delicious viand is prepared, as is well-known, on a large scale in several continental countries by a process of "stuffing" geese with food until the liver undergoes enormous fatty degeneration. The practice is one which has often been condemned, especially on this side of the channel, on account of the supposed cruelty involved in the abnormal conditions of existence imposed on the animal in order to attain the desired result. It would be interesting to note the attitude of the Society for the Prevention of Cruelty to Animals *vis-à-vis* the enterprising persons who begin the experiment. Possibly as the result of it is the production of a well-known and esteemed *comestible*, the officials may consent to shut their eyes—and open their mouths.

Bicarbonate of Sodium in the Treatment of Gonorrhœa.

THE copious discharge which is so marked a feature in gonorrhœa is invariably acid in reaction, and this fact has even been suggested as a test for the nature of the disease. The specific bacillus, moreover, to which gonorrhœa owes its ready and peculiar infectiveness, can only flourish and multiply in an acid medium. Considerations of this kind have led Dr. Castellan, a French army surgeon, to try the effects of alkaline injections into the urethra in gonorrhœa. The results obtained are reported by him to have been excellent. He begins by testing the reaction of the discharge, and then, if acid, injects a small quantity of a one per cent. solution of bicarbonate of sodium, the least irritating of the alkaline salts, repeating the injection several times daily. Under this treatment, the scalding accompanying micturition is at once alleviated, and in the course of a week a very marked diminution is brought about of the discharge. Convalescence was generally rapid, and the final result very satisfactory. The treatment is also applicable to gleet. The good results alleged to have been obtained naturally require to be confirmed by experience before we can call on our neighbour to rejoice. Reiterated disappointment has begotten scepticism, but the plan of treatment has the great merit of being inexpensive and absolutely free from risk. Even if the specific action of the alkaline solutions be not justified by observation, nothing but good could follow the employment of a weak solution of anything.

Convalescent Homes.

These institutions, the multiplicity of which reflects such credit on the kindliness and charity of the English people, undoubtedly do much towards restoring to health the victims of disease or accident. They are the necessary complement of every hospital, and serve to carry out the cure which has been began in the latter. In those homes, however, devoted more particularly to children, there exists a certain risk of infection on account of the previous surroundings of many of the little sufferers, and no stringency nor care on the part of the authorities can insure a perfect immunity. Patients recovering from any of the infectious diseases are, as a rule, considered ineligible as convalescents, but the fact of their having suffered from one or other of the infectious diseases may have been overlooked or wilfully concealed. We have heard of several cases in which the circumstances have seemed to point to infection having taken place during convalescence, and the inability of the authorities to trace the infection only shows the difficulty of enforcing any adequate rules for its prevention. Persons just recovering from the effects of serious illness are presumably more than usually amenable to the influence of disease causing germs, and the greatest care is therefore necessary to prevent their exposure.

Materia Medica and Pharmacy at the London College of Physicians.

The examination in these subjects has undergone considerable modification during the last two or three years, with considerable benefit to the students and their teachers. While they have not been rendered less severe as tests of knowledge, their form has been rearranged so as to be better adapted to the epoch of the curriculum at which they are usually taken. For the present, it is less with the subjects examined upon than with the form in which the questions are put, that we have to do. In the last paper, set on January 5th, the following question is put:—"Give an account of nux vomica, . . . its medicinal action *on the various organs of the body, &c.* Now what do the examiners mean by an "account" of a drug? Do they wish to be told its life history? its botany? its appearance? it is difficult to imagine a reply within the limits of the time allowed, which should comply with such a request. Again, as to its action *on the various organs of the body;* we should like the examiner himself to say what its action is on the liver and kidneys respectively, or on the stomach and intestines. It is so easy to put the same question in a simple, straightforward manner, that we cannot but regret so much ambiguity should have been allowed to creep in. Question No. 2 requires the candidate to enumerate the various forms of alcohol contained in the Pharmacopœia, with their strength. But the list is unduly comprehensive, seeing that not only the various kinds of alcohol may be expected, but tinctures and other preparations into which alcohol enters, from egg flip downwards. It is a pity too, that examiners will continue to ask such comparatively idle questions as the composition of mist. ferri. co., pulv. cretæ aromaticus c opio, &c., &c. Provided the student knows the proportion of the active ingredient, it surely is of little consequence to bear in mind the subsidiary flavouring or diluent agents. Fancy asking a man the proportions of the drugs entering with the composition of the confection or the compound mixture of senna.

What a man wants is a good working knowledge of pharmacy and materia medica, and not the phenomenal recollection of a crowd of unimportant and often ridiculous details. The examiners of the College of Physicians may be excused if they fail to grasp the real wants of the men whose future existence is to be so different to their own, but their lack of judgment militates in favour of leaving such subjects to be dealt with by so competent an authority as the Apothecaries' Society, which is more in touch with the wants of every-day practice.

Chinese Domestics.

A proposal is before the public which may perchance shock the nerves of that estimable person, Mrs. Grundy. It is nothing less than an attempt to remedy the daily increasing dearth of steady, respectable domestic servants by the importation of others from the celestial regions. The scions of this ancient race have given proof of their capacities in this direction in San Francisco and the Western States of America, though it must be confessed they have not invariably been appreciated as their services merited. These servants have the disadvantage of being male, Chinese females seldom or never leaving the old country, and this fact alone may not unnaturally inspire some anxiety until experience shall have proved them more inoffensive than males in general. The importation, however, of large bodies of single men, unaccompanied by women, is one which may be attended by grave prejudice to public and private morality, especially as these gentry do not possess a remarkably good reputation under this head. There is doubtless scope for their employment in this country, but it should be with circumspection and with full consciousness that though bland be their smile, they are by no means exempt from the vices which flourish in other climes.

The Royal College of Surgeons of England.

The result of the questions put to the Fellows of the College in reference to the admission of Members of the College to seats on the Council, and to the vote for members of the Council, has now been published. Some 987 circulars were sent out, to which 706 answers were received; of the latter, 419 were opposed to the admission of members to vote, and 276 were in favour thereof. The majority against the proposed change is therefore 143. As regards the eligibility of Members to seats on the Council, a majority of 354 votes were recorded against it. This result will surprise no one. The deliberately unfair and misleading form in which the questions were put allowed of scarcely any other issue. The *quasi* duplicity of which the College has been guilty, and by means of which it has apparently scored a victory in favour of the *status quo*, will, however, not be forgotten, and the movement, of which this is only an episode, will continue, undeterred by a *scrutin* which leaves matters pretty much where they were before, except that some change in tactics may be judged necessary in view of the oriental diplomacy of the College authorities.

The Death of Lord Iddesleigh.

Most of our readers will have learned with regret the death of this veteran politician and accomplished gentleman, which took place on the 12th inst. Death would appear to have been the result of mitral and aortic disease, causing fatal syncope. Although a medical man was almost immediately on the spot, nothing was of any avail in postponing the fatal termination. The occurrence was not altogether unforeseen, but nevertheless gave rise to a feeling of painful surprise among the public. No inquest will be held, as Dr. Mortimer Granville, his ordinary medical attendant, has certified his death to have resulted from gout, cardiac disease, and syncope.

The Crown Representative of Ireland in the General Medical Council.

We asserted last week that all the statements made in the daily press and in our medical contemporaries as to the appointment of a successor to Dr. Lyons were, if not unfounded, at least premature. The day succeeding our publication, Sir George Porter was offered the appointment, but unhesitatingly declined it, being unwilling to incur the sacrifice of practice which the duties would involve.

We have now to announce that on Friday last Dr. William Moore, Physician to the Queen in Ireland, was offered the appointment, and that he has since accepted it. Dr. Moore will be, undoubtedly, a capable Crown representative, inasmuch as he is thoroughly conversant with Irish medical education and the moot questions which may arise in the Medical Council thereupon. He has, in the College of Physicians, of which he is a Fellow and ex-President, and as their representative on several occasions in Parliament, always taken an independent and liberal view, and shown himself free from the influence of ancient traditions and anxious for progress and necessary reform. He can speak well, and is in every respect a creditable representative of the Irish party in the Council. We could, however, have wished that the successor of Dr. Lyons might be less closely related to the University-Physician party than Dr. Moore's antecedents promise that he will be. Already Trinity College and the College of Physicians have a large predominance in the Irish Branch Council, being represented by Dr. Haughton and Dr. Banks, and we hope we are doing Dr. Moore an injustice in expressing our apprehension that he may reinforce that influence. The coming meeting of the Medical Council will show whether or not our fears are well grounded.

The annual general meeting of the Harveian Society of London will be held to-morrow (January 20th) at 8 p.m., at the Stafford Rooms, Tichborne Street, Edgware Road, when the retiring president, Dr. Hughlings Jackson, F.R.S., will deliver an address, after which a *conversazione* will be held.

A Reputed Anti-Neuralgic Specific.

The number of drugs and combinations thereof recommended from time to time as capable of being successfully employed for the cure of neuralgic pains is only equalled by the frequency with which their vaunted powers are found incapable of controlling the attacks against which they are directed. A prescription, however, communicated by Dr. H. G. Davis to the Boston *Medical and Surgical Journal* seems, at any rate, worthy of trial, it being asserted that it has never failed, in the hands of Dr. Davis, to cure the cases of pure neuralgia occurring in his practice. The mixture is as follows:—℞ Tinct. cinchonæ comp., oz. ii; Tinct. nucis vom., oz. ss; Morphiæ sulph., grs. ii. Of this, one teaspoonful is to be taken every three hours, and as the dose of morphia thus administered is one eighth of a grain, it is not difficult to suppose that, if sufficiently prolonged, the medicine may exert a sedative effect. Dr. Davis, however, implies in his letter that the desired result is obtained after one or two doses, and that it is permanent, in proof of which he cites two cases, both of which had been given up as incurable after having consulted numerous eminent practitioners at home and abroad. He expressly advises physicians who resort to his prescription to use the precaution of ascertaining the strength of the tinctures employed, as many of those sold are, he declares, worthless. A trial of the remedy may well be worth making, for neuralgia is not infrequently a trying difficulty in general practice.

Cold and Fog Mortality.

As illustrative of the effects of cold and fog on the health of the population it may be noted that the mortality rates in some of the large towns have risen nearly forty per cent. within a month. Birkenhead, which on December 18th gave a death-rate of 14·8 per 1,000 has now one of 23·5; Birmingham from 17·1 has risen to 24·4; Brighton from 12·1 to 18·5; Derby 11·9 to 17·2; Edinburgh 18·2 to 26·6; Halifax 21·3 to 30·3; London 18·8 to 26·3; Manchester from 25·0 to 36·4; and at Plymouth the increase during the month has been more than cent. per cent., viz., from 19·8 on December 18 to 40·6 at the present time. Almost without exception the rise in the death tables has been from affections of the respiratory organs; small-pox, typhoid fever, &c., being entirely absent.

Legal Quirks and Drug Frauds.

We referred last week to the ridiculous judgment of the Sheffield stipendiary magistrate to the effect that anything might be sold as "paregoric" or as "tincture of opium," though absolutely devoid of any or all of the pharmacopœial ingredients. He seems to have ruled that, unless the Pharmacopœia article was specifically asked for, the retailer was not bound to supply a preparation of the strength indicated in that work. But the Order in Council, dated February 3rd, 1851, shows that this is not the case. The Medical Act of 1862 provided that any Act of Parliament, Order in Council, or Custom relating to any former Pharmacopœias should be deemed, after the publication of the British Pharmacopœia, to refer to such Pharmacopœia.

But a still more ridiculous interpretation of the law is that of the Solicitor of the Inland Revenue, who, on an interrogation from Messrs. Newbery, gives it as his opinion that an article called "Corn Solvent" need not bear stamp duty, but if called "Corn Eradicator" it must. The *Chemist and Druggist* says:—"We knew before that 'Cough Mixture' was permissible, though 'Mixture for Coughs' could only be used with stamp. Now we learn that the line of liability lies somewhere between 'Corn Solvent' and 'Corn Eradicator'; but the underlying principle is too intangible to be caught by our vision."

The "Jacob" Testimonial.

We are requested by the honorary secretaries to mention that this fund will shortly close, and that they would be glad if intending subscribers would kindly forward their amounts without delay. On reference to our advertisement columns a full list of subscribers to present date will be found arranged alphabetically, for which the honorary secretaries beg thus publicly to acknowledge.

Iodoform and Silver.

A curious effect of iodoform upon silver is reported by Dr. Poncet, who had his attention directed to it by a patient, to whom he had been applying iodoform dressings, telling him that all soups and other diet for which she used a silver spoon had a very disagreeable taste, and the spoon itself had a garlicky odour Upon investigating the subject Dr. Poncet found that silver that has been in contact with iodoform, or which is even touched by the fingers after they have been in contact with iodoform, acquires a nauseous odour, resembling that of garlic, which becomes more perceptible upon rubbing the silver. A drop of saliva from a patient fully under the influence of iodoform is said to be sufficient to impart this odour to silver, or the mere exposure of iodoform and silver in the neighbourhood of one another. The odour is not that of iodoform, but is thought to be due to a decomposition product.

The Mercer's Hospital Inquiry.

We understand that the inquiry by a committee of the Dublin Corporation into recent occurrences in Mercer's Hospital and into the charges and counter-charges made with reference to the treatment of a patient named Farrell in the hospital, and the conduct of the matron and house-surgeon, and of an ex-student thereat, was fixed to take place yesterday (Tuesday). The wife of Farrell, who died immediately after being taken out of the hospital, has, however, taken out police-court summonses against the matron and house-surgeon for assault on the occasion, and the case is fixed to be heard also on Tuesday, which may have the effect of adjourning the Corporation inquiry. The committee appointed for the purpose by the corporation are Sir George Owens and Alderman Byrne, both gentlemen who may be depended upon to do what seems to them to be just. We trust that the inquiry will be thorough and exhaustive, and that there will be no hesitancy in fixing the blame where it should lie. Already the hospital has been brought into great disrepute by the attempt to cushion the charges made rightly or wrongly against its officers, and it is now obviously best that a clean breast shall be made of the whole affair. Mercer's Hospital has been for years going from bad to worse, and is in imminent danger of total collapse both as an educational and charitable institution. A drastic purgative is necessary.

The Queen's Jubilee Hospital.

It was with a feeling bordering on incredulity that we received the announcement of the foundation of another new hospital in London. It scarcely appeared to us possible that any body of persons could be possessed of sufficient audacity to venture on floating such a scheme, at a time when existing hospitals are groaning under the burden of lessened incomes and increased expenses, and when the whole question of hospital management awaits serious consideration. With the secretary's letter before us, however, we are reluctantly obliged to recognise the fact that such an attempt is being made, and that advantage is endeavoured to be taken of the jubilee of Her Majesty to throw a halo of patriotism around the project, and so facilitate the financial part of the undertaking. The device is one which can do little else than elicit expressions of contempt from all intelligent persons. It is as much to be deprecated as the religious protestations which make one man call his physic-shop the "Congregational Dispensary," and another, the "Methodist Medical Institution." The new hospital is stated to be intended for the treatment of those cases "which general practitioners as a rule do not care to treat." We have yet to learn that there are such cases which could not be adequately treated at existing institutions, although the list of organs which the general practitioner is credited with a disinclination to treat is tolerably comprehensive. Diseases of the "throat, ear, skin, eye, rectum," and, as if the list still lacked scope, "various deformities of the human frame." *Merci!* there is not very much left to tamper with when the above are subtracted from the sum total of other than visceral disturbances. The hospital, it will be seen, is intended for the treatment of special complaints, but its organisers, not satisfied with one or two specialities like most of its congeners, prefer to embrace them all. Now, if there be one description of hospital in London the number of which, from every point of view, it is undesirable as well as unnecessary to augment, it is the class to which the proposed hospital would belong. In the majority of cases these special hospitals have degenerated into mere nurseries for patients for the presiding geniuses, and their participation in the various funds subscribed by the public for the maintenance of hospitals generally has been held to be little less than a scandal. The very locality chosen for the site of the new hospital—Gloucester Terrace, Queen's Gate, S.W.—militates against its *raison d'etre*. One would have thought that the inhabitants of that district would, of all others, be in a position to consult and pay a medical man, and failing adequate treatment at his hands, to consult a specialist. The assurance is given as a matter of course that every endeavour will be made to prevent any abuse of it, but with our experience of similar institutions before us, such assurances have but little weight. Upwards of a million people are treated in the out-patient department of the metropolitan hospitals annually, and it cannot be desirable to add to their number. On the above grounds we view with the greatest dissatisfaction the scheme which has been communicated to us, and we cannot but hope that the proposal will meet with the disfavour which, in our opinion, it and all similar schemes merit at the present juncture. The jubilee of Her Majesty offers an excellent opportunity for placing the financial administration of hospitals on a better and more permanent footing, and it cannot be considered good or patriotic policy to divert attention—and contributions—from the main object in view.

Dublin Branch of the British Medical Association.

THE tenth annual general meeting of the Branch will be held on Thursday, 27th, in the College of Physicians, Kildare Street. The officers and council for the ensuing year will be elected by ballot. Dr. T. W. Grimshaw, Registrar-General for Ireland, and President-elect, will deliver the annual address. The annual dinner of the Branch will be held in the College Hall on the day of the meeting.

The House of Industry Hospitals.

ON Thursday last the Board of Governors of these Hospitals elected, in the room of Dr. Lyons, Joseph Francis O'Carroll, M.B, Assistant Physician of the hospitals. Dr. O'Carroll is a Demonstrator of Anatomy and Histology in the Medical School of the Catholic University.

DR. DALTON, of Oranmore (Galway), who was arrested some months ago for assaulting the police, was last week tried and acquitted, while his accusers have been committed for trial for assaulting and wounding him.

WE regret to observe that the Westmeath County infirmary at Mullingar, a most valuable local hospital, has only escaped extinction by the casting vote of the Chairman of the Presentment Sessions. We need hardly observe that this onslaught on the institution is only part of the general movement for the extinction of county infirmaries, which has been pressed forward by the "popular" party, and it seems reasonable to expect that when the grand juries give way to the proposed county boards, most of these institutions will be closed.

◆

Germany.

[FROM OUR OWN CORRESPONDENT.]

THE ÆTIOLOGY OF TYPHOID FEVER.—One of the most recent and most also interesting studies on the above subject, is that of Dr. Karl Seitz, Assistant in the Medizinischen Poliklinik, Munich. The material for study was afforded by 11 cases of typhoid. Examination of the blood drawn under all antiseptic precautions from the fingers and rose spots of fever patients showed no typhoid bacilli,—contrary to the statement of Meisel; the same was the case with sections of the rose papillæ. From this he concludes that if the bacilli circulate in the blood at all, and this has not yet been proved, it is only very sparingly.

The dejections were examined 24 times (19 times with 6 cases), in 8 cases with a positive result both in the 2nd and 3rd weeks of the disease. He made also disinfection experiments that gave the result that 5 per cent. solutions of sulphate of iron, and chloride of lime, 1 in 2,000 of sublimate and hydrochloric acid of the same strength as in the gastric juice were absolutely insufficient to destroy the germs of the disease; whilst on employing a 10 per cent. solution of carbolic acid, or a 5 per cent. solution of sulphuric acid, no colonies developed. The urine was always free from them except in two instances, in both of which a good deal of albumen was present, implying some want of integrity of the urinary tract.

In twenty out of the twenty-four bodies examined microscopically in one or more organs the characteristic radiate patches, or capillaries filled with bacilli, were met with. In one case complicated with erysipelas numerous patches of erysipelas cocci were met with in the spleen. The bacilli were most frequently present in the mesenteric glands, the spleen, more rarely in the liver or kidneys. Characteristic patches were also present in non-ulcerated, indurated Peyer's patches, a fact which was taken as implying that the bacilli entered by way of the intestinal tract. It was clear that the bacilli continued to increase in the body after death, as they were the more numerous in the spleen the longer was the time allowed to elapse *post mortem* before putting it in alcohol.

The only certain mark of identification of them is their typical mode of growth on cultivation. If cultivated on the surface of a piece of sterilised potato, they grow gradually, spreading from the point of inoculation in the form of a spreading moist covering, in which, however, the surface of the potato itself is not in the least changed In hanging drops the bacilli show lively serpentine movements. Both milk and urine proved suitable soil for their growth, but in acid urine after six days a marked diminution took place in their number. A low temperature (3° C.) delayed their growth; no experiments were made as to the influence of continued fever heat. The common antipyretics (quinine, antipyrin, karin, thallin, potassic iodide, chlorate of potash, salicylic acid, and calomel) completely arrested the development of colonies in alkaline bouillon; naphthalin, on the contrary, did not. They completely resisted drying, as cultivations kept from August 26, 1885, to April, 1886, had not lost their power of propagation. They can increase in number in the intestinal canal. The author performed numerous experiments on guinea-pigs and rabbits with the view of ascertaining the infective power of both fæcal matter and pure cultivations. Both were very destructive when given by the mouth; in more than 5 per cent. death took place within forty-eight hours, and not only were bacilli of typhoid not unfrequently found in the contents of the intestines, but in several cases infiltration of Peyer's patches and swelling of the spleen were present. In one case pure cultivation of typhoid bacilli were obtained from the spleen and liver. When the infection took place by way of intravenous injection, the bacilli were never met with in the intestine, but in one case they could be cultivated from the liver and spleen.

Dr. Seitz concludes from his experiments that the portal of entry of the bacilli into the system is probably the intestine, and that the two facts, viz., (1) that no anatomical changes are met with in the lungs; and (2) that when the micro-organism, are injected into the blood current they do not find their way back into the intestine, are strong evidence that the poison does not enter from the pulmonary tract,

Scotland.

[FROM OUR OWN CORRESPONDENTS.]

Edinburgh University.—Death of the Lord Rector.—The news of the sudden death of the Earl of Iddesleigh produced a profound impression in Edinburgh circles. More especially was this the case among the members of the University, whose Rector the late nobleman was. Professors and students alike were overcome with grief when the sad report was confirmed. It will be remembered that Lord Iddesleigh was, in November last, chosen by the students, for a second term of three years, as their academic head. The honour, seldom twice granted, was accorded with the utmost enthusiasm to one, who by the display of sympathetic interest in all that concerned his constituents, and of a high toned, courteous bearing had endeared himself to the students. This is the first occasion on which the University has had to mourn the death of its Rector, and a certain amount of doubt prevails as to what course may be followed in consequence. A literal rendering of the statute suggests that the students remain academic orphans till November next. But legal opinion may possibly authorise the earlier filling of the sad blank. Most of the professors and lecturers made reference to the mournful event on meeting their students on Thursday. The universal tribute was that of the highest esteem and veneration.

Opening of a Class of Practical Hygiene in the Edinburgh University.—A practical class in connection with the chair of Medical Jurisprudence and Public Health has been commenced under the inspiring superintendence of Professor Sir Douglas Maclagan, arrested by Mr. Hunter Stewart, M.B., B.Sc. The attendance is sufficiently encouraging to make the class one of the established institutions of the University. If the University is to keep pace with the development of modern medicine, she will have to widen her basis and extend her status in many similar directions. It is the gravest mistake possible to curtail the number of these accessory classes, while it is a no less grave error to insist on making any of them compulsory.

The Reporting of Infectious Diseases in Edinburgh.—The Town Council has received the half-yearly report of the returns of infectious diseases within the boundaries of its jurisdiction. The general opinion expressed by the members was one of complete satisfaction with the manner in which the new regulations are carried out. The Council was unanimously of opinion that the money expended on the recording of the cases was well spent, while the citizens' rights were nowise infringed. Some discussion arose on the question of the payment of fees of doctors called in cases of accident. The Council felt it could not interfere with the old arrangement, while expressing the opinion that the matter was one which properly belonged to the sphere of Dr. Littlejohn, the surgeon of police.

Police Cases and Medical Men.—The recent death of a man in the streets of Edinburgh from the effects of a stab has excited a good deal of attention from the fact that, if the reports are to be believed, two medical men on being applied to refused to dress the wound, and referred the injured man to the infirmary, before reaching which he died. We need not here explain, justify, or condemn the action of the medical men applied to. The importance of the incident lies in the fact that it may give rise to the institution of "night service doctors," similar to the plan which has been in practice with great success in Paris for some years past. If certain men were appointed at a fixed tariff, recoverable either from the patient or in his default, from the municipality, a long and exhausting journey to the police station might be avoided. Medical men cannot reasonably be expected, failing some such arrangement, to get up at all hours of the night to attend to the victim of, it may be, a drunken brawl without any assurance of fee or reward. Such an institution is greatly needed in London, Dublin, and other large cities, and must sooner or later be established.

A Scotch Judge on Medical Evidence.—In summing up in the trial of an action raised by a Glasgow horse-dealer against the Caledonian Railway Company for compensation for personal injuries, Lord Fraser used some very strong language in reference to the medical evidence. He remarked that the pursuer had been injured in the arm and leg, and his own doctor had said that he did not think the injury to the arm was a permanent injury, and that what he was suffering from at present was crutch paralysis. Then came the other question as to the leg, and here there had been exhibited, much to the disgrace and the discredit of medical science, a most extraordinary difference of opinion in regard to matters visible to the commonest understanding. He would not venture to express the indignation with which one must have listened to the evidence given by the doctors in this case. There were four doctors for the pursuer, three of whom were well known in this Court—Dr. Littlejohn, Dr. Joseph Bell, and Dr. Cameron—all men of repute and renown in their profession of learning and respectability, and Dr. Halkett, who had given his evidence in a way that commended itself to their favourable consideration in admitting his own practical unacquaintance with surgery. They had these four gentlemen saying that there was rupture of the muscle, that the rupture was a permanent injury, that although the gap caused by the rupture was now filled up it would never be as it was before; that the leg had lost its elasticity, and that the muscle had no longer its contractile power. That evidence was met by three doctors on the other side—Dr. Dunlop, Glasgow; Dr Heron Watson, Edinburgh; and Dr. M'Leod, Glasgow. The defendant railway company employed a most zealous agent, Dr. Dunlop, but he wished that the doctor would couple with that great zeal of his a little of sense, judgment, and discretion. They had had evidence from him yesterday that this man, who could not put his foot to the ground, should go on horseback and gallop as the best thing for the calf of his leg. One could not attach much stress to Dr. Dunlop's evidence in the matter. The other two doctors were men of great repute—the position which they held showed them to be that. It would be a profitless task on his part to go through the notes of the evidence of these medical men, or attempt either to reconcile their preposterous contradictions or to say which was the best. The jury had heard the evidence as well as himself, and were as capable of forming an opinion upon which side the truth lay.

Glasgow Health of the City.—At a meeting of the Town Council of Glasgow held on the 10th inst,: Dr. Russell submitted his annual and fortnightly reports, from which it appears that during the year 1886 there were 13,099 deaths registered, as compared with 13,486 in the year preceeding, a decrease of 387, representing a death-rate of 25 (25·1) in place of 26 (25·9) per 1,000 living. Since the Public Registration Act took effect, the death-rate of Glasgow has never been less than, or as low as, in 1886, except in one year—viz., 1879, when it was 24·6, or 5 per 1,000 less. In his report for the past fortnight, Dr. Russell remarks as a coincidence that the solitary case of typhus occurred in the person of a medical practitioner, who is now under treatment in Belvidere Hospital for Infectious Diseases. It is many years since a medical man in Glasgow has had typhus, whereas in the earlier days of Dr. Russell's connection with the service it was common, and many lives were lost from time to time.

◆

Literature.

RECENT WORKS ON THE EYE.

I.—*The Refraction and Accommodation of the Eye and their Anomalies.* By E. Landolt, M.D., Paris. Edinburgh: Y. J. Pentland. 1886.

PROFESSOR DONDERS' masterly treatise on "The Refraction and Accommodation of the Eye," published some twenty years or more ago, gave a remarkable impetus to practical ophthalmology. It is now admitted generally, that in order to treat eye diseases successfully an intimate knowledge must be acquired of their optical construction and functions, since a large proportion of the patients who consult the ophthalmic surgeon suffer more or less from optical disturbances. With these facts before us, and seeing the enormous strides made in ophthalmology during the last two decades, we have felt surprise that Donders' work has not attained to a second or a revised edition. The reason is not far to seek, it is too mathematical for the majority of those among us, who instinctively shrink from algebraic formulæ. This fault scarcely applies to the treatise before us, since the author has not found it necessary to go beyond "that elementary knowledge of mathematics which is so quickly forgotten." Furthermore, he, so to speak, separates this portion from the rest, and devotes a short introductory chapter to formulæ which will be thought necessary to elucidate the subject by those who take a particular interest in the scientific solution of questions under consideration. Dr. Landolt, however, is known to be a reliable teacher of modern physico-physiological ophthalmology; he writes from a thorough acquaintance with the intricacies of the subject, and may be trusted as a careful exponent of the labours of his predecessors. His volume consists of 600 pages, and is divided into three parts; the physical, the theoretical, and the clinical. In the physical he traces the luminous point emitting its undulations, and follows up the subject to its logical conclusion. The *rationale* of refraction is clearly explained as well as most other problems involved in ocular optics. The practical being ever kept in view. In setting forth the relations between the old and new systems of numbering lenses, two useful tables are introduced which show at a glance the relative value of spectacle glasses according to the former method of numbering, or focal distances, and that of the metric or dioptic. To those who still object to the change of system these tables will be acceptable, as in reading the more modern works in ophthalmology, the numbering according to the refractive power of the lens and that of focal distance is seen at a glance. The theoretical portion of the book deals with the optical properties of the eye under all conditions of refraction. The principles of optometry are explained, but no opinion is given of the merits of the several optometers in use, the reason of this is obvious enough. Reference is made to the estimation of the shadow-point, under the heading Koroscopy; this is evidently not considered of much practical importance, although there are those who pretend to determine refraction with the aid of the shadow which the cornea projects upon the pupil. Landolt observes, however: "I never could well understand this way of considering the matter. Certainly every light involves a shadow, but since I use the ophthalmoscope to throw light into the eye, and not a shadow, I find it more natural to fix my attention upon the former than upon the latter." With reference to the method of determining amplitude of accommodation, we find that in practice accommodation and convergence, and the several relations existing between the two functions, so necessary for the perfection of binocular vision, these have not hitherto been sufficiently considered or taken into account. They have, undoubtedly, been reduced to greater simplicity since the introduction of the metric system into ophthalmology, and which has given to accommodation as a standard the dioptry, and to convergence the metro-angle. The method of determining refraction and accommodation by the aid of test lenses is very clearly explained.

The disorders of convergence are ably treated, and Landolt's views on this subject are of great practical value: Astigmatism although it occupies a special chapter is imperfectly treated of. That form of corneal astigmatism resulting from operations, and which often is attended with an amazing degree of astigmatism is more particularly dwelt upon. In extraction, for example, after the thorough healing of the wound in the cornea it is seen to be persistent and very troublesome to correct. The troubles occasioned in this way are again referred to at some length in the clinical part of the book. Landolt somewhat sarcastically says "aphakic vision is so complicated, while enucleation simplifies so many things, even a successful operation often becomes a source of annoyance to the operator from his inability to surmount all the anomalies of an aphakic patient's vision." This is a truism. The clinical portion of the book occupies nearly one half as it should, since it is of great value to the practitioner. The refractive conditions of the eye are classified under the usual headings of hyperopia, emmatropia, and myopia, but we notice in particular that Landolt's treatment frequently differs from that adopted in this country. He very emphatically insists that "we are not to suppose that, whenever an eye does not have its principal focus on the retina, it ought to cause anxiety, and demand optical correction or even medical care." This warning is needed by those who prescribe glasses for every trifling anomaly of vision, and especially for children whose vision is likely to be permanently injured by having had too deep glasses prescribed. The majority of eyes only slightly hyperopic and myopic are no doubt perfectly healthy, and Landolt would leave a considerable amount of hypermetropia uncorrected so long as the accommodative power is fairly good. In treating myopia he says:—"a myope must be prohibited from wearing a concave glass for any distance at which he can see clearly without accommodation." For the most part a slight myopia demands clincal intervention in an exceptional number of cases. Typical hyperopia should be looked upon as arising from an imperfectly developed organ in all children under eight years of age. Eyes become emmetropic or myopic only when later on the body has acquired its full development. This is an important practical generalisation. The symptoms of typical hyperopia, clearly and precisely given, are sometimes seen to develope themselves in the course of diabetes. Landolt refers to a case in which refraction increased and diminished according to the amount of sugar excreted. As the sugar disappeared the patient could dispense with her distant spectacles.

In hyperopia it is the refractive defect that constitutes a true anomaly. The hyperopic eye being absolutely too short, the myopic eye on the contrary being too long, for great distances, while it is perfectly adapted for near vision. If hyperopia represents an arrest of development of the eye, typical myopia is a state created by nature with the view of adapting the organ to the functions of a superior race; at all events myopia so far is observed to be peculiar to the human race, and in a general way the tendency to it may be regarded as a phenomenon of adaptation to the exigencies of the development of the species. Under atypic myopia we have progressive, pernicious, and malignant myopia, formerly diagnosed as a progressive myopia associated with staphyloma posticum; the ophthalmoscopic appearances of this anomaly are characteristically portrayed in coloured drawings and woodcut illustrations. The disease is believed to be congenital, but Landolt says that statistics do not support this view, as the affection is rarely observed before the age of eight or ten, the greater progress being between the ages of twelve and eighteen, since it is between these ages the eye acquires its final form, and consequently its abiding static refraction. Amongst the determining causes of myopia near work is, our author says, the most frequent. Close work requires a much greater effort of the ciliary muscles than distant vision. The reason "why watchmakers and others are so rarely found among myoptics is quite capable of a satisfactory solution." With regard to its unfrequent production by school work, it is reported that in three years after the building of the Coburg schools on hygienic principles, the number of myopes decreased from 21 to 15 per cent., and in the new schools of Geissen a decrease of 6 per cent. took place. The rules formulated for the hygienic arrangement of the school, as well as the proper disposition of school accessories, are in every way judiciously designed for avoiding influences which contribute to myopia in children. Landolt directs attention to a fact in connection with progressive myopia, probably of more importance than it is usually supposed to be, namely, the great change in the amount of accommodation required when a slight variation is made in the position of an object held near to the eye. The greater demand in such a case upon the ciliary muscle in particular is a constant cause of asthenopia, and of an increasing myopia.

There are very many points of great practical interest which we had marked for quotation, but the space at our command is exhausted. We cannot conclude, however, without adding a few words of commendation on the thorough excellency of the translation. Donders is said to have been fortunate in his translator, but Dr. Landolt is even more fortunate in having found a former pupil, Dr. Culver, well acquainted with his master's methods of practice, and so able in every way for the task. The publishers deserve praise for the typographic excellence of the book, and the superiority of the illustrations, those showing the ciliary region in particular. A very full and carefully prepared index gives increased value to the work as one of reference.

II.—*Short Sight, Long Sight, and Astigmatism. An Elementary Guide to the Refraction of the Eye.* By G. F. Helm, M.A., M.D., F.R.C.S. London: Churchill. 1886.

There are manuals and manuals on ocular physics, and for the publication of some of which no good reason can be assigned. Dr. Helm in his preface, however, tells us "the object he has in view is that of placing before the student and practitioner an elementary treatise on the errors of refraction of the eye," and "it is intended also to serve as an introduction to the more advanced manuals on the subject." If this be the case, it is difficult to conceive why the elementary laws of optics, find no place in his pages. Chapter one is devoted to the passage of rays of light through lenses, and here his diagrams (which we can hardly supposed were prepared for his text), rather tend to make confusion worse confounded, for the supposed rays of light in most of them pass outside and not through them. In chapter two he proceeds to definitions; the eye, he tells us, is made up "of certain refractive media, cornea, aqueous humour, and lens, which together possess the same power of refracting rays of light as does a + lens," meaning we suppose, to liken one of the media to a lens. A bald statement of this kind might well lead the student to attribute a great deal too much power to the lens, and which is known to be comparatively slight, the chief refraction taking place at the surface of the cornea. Here the rays receive their convergence, which are little more than continued by the crystalline, whereas in a + lens most of the convergence occurs as the rays quit its posterior surface and emerge from its anterior surface. Further on an attempt is made to define the meaning of visual angle, but the student will not derive much satisfaction from being told that "in the normal eye the visual angle subtends an angle of five minutes," and the diagram again in no way assists to make this clear. The visial angle increases and diminishes according to the magnitude and distance of the object, while the size of the image on the retina determines the apparent magnitude of the object, and the angle which the image subtends is in constant but unknown ratio to the visual angle. An increase in the visual angle is brought about by the aid of a + lens, but we are not certain that Dr. Helm, when he writes of visual angle, means the same as we do; at all events we cannot be expected to correct all the errors of an author who, in an elementary treatise, thinks it right and proper to omit all reference to the value of ophthalmoscopic examination, of retinoscopy in particular, in estimating and correcting errors of refraction.

III.—*The Normal and Pathological Histology of the Human Eye.* By C. F. Pollock, M.D., F.R.C.S.E., &c. London: Churchill. 1886.

Dr. Pollock has evidently bestowed a great amount of time and care in the preparation of his manual on "The Normal and Pathological Histology of the Eye and Eyelids." No less a number than 230 drawings made from selected and typical preparations are reproduced in lithography, all with a finish and fidelity equal to those with which Pagenstecher has made us familiar in his well-known "Atlas of the Pathological Anatomy of the Eye." We fear, however, that Dr. Pollock's work will not realise all his expectations, namely, that it will take a place among students' text-books. In the first place it is published at a price much above that of the ordinary manual, and in the next place black and white, or even tinted illustrations of complicated and delicate tissue changes can not be made to convey the same amount of information or instruction as carefully prepared specimens viewed under the microscope. Dr. Pollock seems to labour under an impression that the manual and pathological histology of the eye is not generally taught in our medical schools. His words are "practical instruction in the subject is not generally available." We need scarcely say that these remarks do not apply to the London schools, where a systematic training is generally pursued. The text of the book bears the impression of having been pared down to make room for the illustrations, and only about half a dozen lines are devoted to the author's methods of staining, hardening, and preparing specimens. These are defects in a manual intended for students, and which otherwise embodies the valuable results of many years of labour undertaken with a view of rendering the normal and pathological histology of the eye more generally available to students and the profession.

IV.—*Sketch-Book for Ophthalmological Observation of the Fundus of the Eye.* By Dr. O. Haab. London: Trübner. 1886.

Dr. O. Haab's "sketch-book" is designed to facilitate and encourage clinical note-taking and sketching, both in the consulting room and in the wards of the hospital. The book consists of a number of leaves or tablets partially prepared ready for use, upon each of which is faintly printed a red outline of the optic disc and larger vessels. A chalk pencil of two colours, and a rubber, together with directions for use, are comprised in the small space of a pocket-book. This sketch-book will doubtless be in great demand by the large body of clinical clerks attached to our hospitals.

◆

THE LAST INTERNATIONAL MEDICAL CONGRESS. (a)

The proceedings of the third International Medical Congress have at last been published, in four volumes of convenient size. Some explanation is given of the delay, which, however, does not comprise any circumstances not present in all similar undertakings. Exception may be made, however, in respect of the death of the President, Professor Panum, of Dr. Salomon, Inspector-in-Chief of the Sanitary Department of the Danish Army, and President of the Section of Military Medicine, and of Dr. Holmer, of the Section of Surgery, all of whom have died during the course of preparation of these volumes, and to whose memory they are inscribed.

The Transactions are published, as is usual, in French, German, and English. The first volume contains the opening address, the regulations, and a list of the members of the Congress, in which are to be found a fair sprinkling of English names; also papers by Messrs. Pasteur, Tommasi Crudeli, Verneuil, Gull, Virchow, and Panum, &c. Some of the papers are illustrated by beautifully designed and executed drawings, notably those by Hermann (Lille) on the Morphology and Development of Spermatozoids; by Engelmann (Utrecht) on the Movement of the Coni and Pigment Cells of the Retina under the influence of light and nerve power; on the Condition of the Heart after Death, by Dogiel (Kazan). Volume II, which comprises the transactions of the Sections of Medicine, Surgery, and

---

(a) "Compte rendu du Congrès International des Sciences Medicales," Copenhagen, 18·4, par C. Lange. Secrétaire Général. (London: David Nutt.) Copenhagen: Librairie Gyldendal.

Midwifery, also contains an admirable plate illustrating the paper on the Alterations of the Red Blood Corpuscles in Malarious Affections, by C. Tommasi Crudeli (Rome). Volume III comprises the sections of Ophthalmology, Pediatrics, Dermatology, and Psychology. The series of papers on ophthalmology are of especial value, and take up the first 225 pages. Volume IV, contains the papers read in the Section of Laryngology, Otology, State Medicine, and Military Medicine.

The whole work is well edited and carefully revised. The type is clear, and numerous intercalated woodcuts serve to aid the comprehension of the more recondite parts. It is rather to be regretted, however, that the editors have not thought fit to append an index, the place of which is only imperfectly taken by a chronological table of contents at the beginning of each volume. Such collections of papers are of very great value, and must add greatly to the completeness of any medical library.

◆

At the Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Few papers recently read have possessed greater interest and importance than that communicated to the last meeting of the Royal Medical and Chirurgical Society by Mr. Bland Sutton on the suture of divided nerves; and that this was fully recognised at the time was shown in the fact that the ordinary time of these meetings was, on this occasion, extended for half an hour, owing to the number of those who joined in the discussion. Mr. Sutton's paper was founded on the history of a case in which a porter, through the accidental bursting of soda-water bottle, sustained a deep wound of the wrist, by which the median nerve had been severed. Ten weeks after the accident the divided nerve ends were freshened and sutured together, with the result that sensation, previously abolished, began to return five days later, and subsequently complete restoration ensued, both of motion and sensation. The author emphasised, as a prominent feature of the case, that the ends of the nerve were readily found by adopting the teachings of experience acquired during performance of neurotomy in horses, a fibrous band being the guide to the structure in question.

The discussion was opened by Mr. Howard Marsh, whose testimony was entirely favourable to the view that such operations as had been described were very frequently successful, his conclusions being based on the success attending them when performed by himself and colleagues at St Bartholomew's Hospital. This satisfactory estimate of the value of nerve suture was maintained likewise by Mr. Holmes, the next speaker; but he took exception to the statement that the fibrous band mentioned by Mr. Sutton could be relied on as a guide in the human subject. On the contrary, he (Mr. Holmes) considered the cases few in which the nerve could be clearly defined; but, notwithstanding, he insisted on the prime necessity for operating when division of the nerves occurred, and he instanced a strikingly successful case in which union of a severed musculo-spiral nerve occurred many months subsequent to division.

Mr. Sutton's deduction from studies in comparative anatomy was opposed also by Mr. Bowlby, who further sought to temper the enthusiasm of the meeting by impressively cautioning it against adopting the assurance of success until years have proved it to be permanent. He was anxious to have more information than had been vouchsafed as to the condition of the muscles in the affected limbs, and volunteered the information that a return of voluntary power was the first sign of restoration in these cases. On the question of the time for suture, Mr. Bowlby sanctioned the operation under any circumstances, being guided to this conclusion by the records of improvement after secondary suture performed as long even as fourteen years after the accident demanding it.

After some reference to a successful case of Mr. Barwell's by that gentleman and Dr. W. H. Murray, Mr. Hulke drew attention to the means adopted abroad for promoting continuity in nerves of which the severed ends were much separated. He referred to the use of sheep's and dog's sciatic nerves in this connection, and the various other methods employed, including side splicing of the nerve ends themselves. Mr. W. Haward instanced a remarkable case, and claimed advantages in the treatment of shampooing, friction, and exercise as aids to the restoration of health.

The only other paper read at this meeting was one also of unusual importance, on the physiological effects of massage by Mr. Symons Eccles, Dr. Lauder Brunton communicating it. The paper describes four separate manipulations, and explains the effects produced by each on the body, the subjects of experiments having been, in all cases, healthy. In opening the discussion Dr. Hermann Weber insisted on the importance attaching to the supervision by medical men of the masseur's operations, a point fully recognised also by Dr. Playfair subsequently, this latter physician citing numerous instances in which the most beneficial results were secured through the process. The necessity of medical supervision was part of the burden of all the other speakers on the paper as well, including Mr. Howard, Dr. Douglas Powell, and Professor Arthur Gamgee. The testimony of each, too, went in full support of massage carried out in a scientific manner, and the whole tenor of the debate strongly confirmed the favourable estimate of its value generally held.

MEDICAL SOCIETY OF LONDON.

The second Lettsomian lecture was delivered on Monday last, by Dr. Langdon Down, on the causes of idiocy or feeble-mindedness in children. Beginning with the "accidental" variety, he remarked how few resulted from injury due to instrumental interference at birth. In not more than three per cent. of feeble-minded children had instruments been employed. More effective in inducing feeble-mindedness was probably delayed birth and prolonged pressure Twenty per cent. of the feeble-minded children he had met with had a history of suspended animation at birth. First-born children were naturally more liable to this. Insolation in infancy was an undoubted cause of a weak-mindedness, a very good example of which he had at present under his care. He attributed but a small influence to the administration of opium by nurses, but said that the latter often contributed to the untoward result by provoking a morbid sexual erethism in their charges. Meningitis, whatever its etiology, was a prolific cause of idiocy, and its influence was often and clearly demonstrable. Epileptiform convulsions, whether eclamptic or not, frequently caused accidental idiocy. Ephemeral causes, such as worms, or whooping-cough, might thus leave a lasting stain, or at any rate a predisposition to a great evil. Hydrocephalus generally caused the congenital form of idiocy, but sometimes the accidental. Paralysis arising from cerebral hæmorrhage was a cause of accidental as well as of congenital idiocy, but the amount of the damage in these cases varied very greatly.

Turning to "developmental" idiocy, the state of the maternal health during pregnancy was of very great importance, especially if the deviation took place about the sixth or seventh month. The causes which, occurring early, produce congenital, operating later, produce developmental idiocy. As to heredity, in only 16 per cent. of the parents did his inquiries fail to elicit a grave history of physical or psychical decadence on one side or the other. Disparity of age between husband and wife has been credited with some influence in the production of intellectual feebleness, but statistics do not authorise more than a slight effect to this cause.

Twenty-four per cent. of 2,000 idiots examined by him were first born, and it was noticed that women having given birth to an idiotic child had an average of seven children. Two per cent. only of the cases were twins.

The lecturer insisted on the importance which he attached to the *emotional* life of the mother during pregnancy. In 32 per cent. of his cases there was a well ascertained history of great mental disturbance on the part of one of the parents. The physical health of the mother was also of importance. In 20 per cent. there had been marked physical disturbance. Vomiting in excess was also possessed of some influence in this direction. Many observations point to the ill effect of alcohol on the production of feeble-minded children. The lecturer's inquiries as to the influence of syphilis have led him to attribute but small importance to that disease.

Emotional disturbances in the father were also apt to exert an influence on the offspring in the direction of feeble-mindedness.

With reference to the proportion of idiotic children born of fathers belonging to the various professions, he does not consider them altogether reliable. An analysis of the observations showed that 3 per cent. were the children of lawyers, and 4 per cent. the children of medical men. No less than 18 per cent. were the offspring of members of the clerical profession. He alluded rather humorously to the causes at work in the production of these statistics.

With regard to the effect of consanguinity in marriage on the birth of idiotic children, he was disposed to consider that the picture had been too highly coloured. About one per cent. of marriages take place between first cousins. Among the Hebrews, Persians, and ancient Egyptians, incestuous marriages were tolerably frequent, but produced apparently no harmful results. Out of 852 cases of known parentage, 60 were children of consanguineous marriages, *i.e.*, about seven per cent., and many of the cases were fairly attributable to one or other of the causes alluded to above, quite apart from any consanguinity in marriage. Healthy consanguinity yielded no such results so far as could be ascertained. He thought, therefore, that while the marriage of cousins of a bad stock ensured a degenerate offspring, the judicious selection of cousins might have for effect to improve the race.

Illegitimacy might fairly be credited with a certain influence from the natural anxiety of the mother under the unfortunate circumstances of her pregnancy.

Idiocy might be produced by mere deprivation of the senses, but it was not inevitable so long as no actual cerebral lesion existed. Cretinism was possessed of a very evident power in preventing or hindering the development of the mind. Passing on to the question of the day, the higher education of women, he said, "if there were one thing more certain than another about the production of idiocy, it was the danger which arises from the culture of only the emotional side of a woman's nature." He thought it would be to everybody's advantage if women were not only "mothers of men," but also companions and helpers of men.

THE RESIDENCY OF THE ARMAGH ASYLUM.

In noticing the recent appointment of Dr. Graham, of Belfast, to this office, we objected to the selection which had been made on the ground that Dr. Graham had seen no service in the Irish Lunacy Department, and had, therefore, been improperly promoted over the heads of assistants in the service. In justice to Dr. Graham and to the Lord Lieutenant who appointed him, we feel bound to acknowledge that we committed an error in confounding with Dr. Graham another gentleman of the same name also resident in Belfast. The new Resident Medical Superintendent at Armagh, Dr. Graham, had served as assistant under Dr. Meyrick in the Belfast Asylum, and, therefore, possessed, to some extent, the special knowledge of the asylum system which, we insist, should be the chief qualification for the office of Resident.

We regret the error, which arose from our determination, so far as we can, to support, against all outsiders, the right of assistants to promotion to the residency.

◆

STRUCK OFF THE ROLLS

We understand that both the College of Surgeons and the College of Physicians of Ireland have cancelled the diplomas held from them by Mr. William Edward Robson, who appears in the Medical Register as of "Estate House, Dundalk," but has resided recently at New Englefield, Staines, Middlesex. The Colleges have taken this course in consequence of the persistent breach of their by-laws by Mr. Robson, by allowing his name to be advertised in a highly objectionable manner in connection with "Warner's Safe Cure," and also in having caused to be circulated handbills laudatory of himself in Sheffield and elsewhere. We believe that the Colleges, before notifying to the Medical Council their withdrawal of Mr. Robson's licence, afforded him every opportunity to express regret, and give assurances that he would conform to their by-laws, but did not elicit from him any satisfactory reply.

◆

THE IRISH POOR-LAW SUPERANNUATION BILL.

The Council of the Irish Medical Association held a special meeting yesterday (Tuesday) to concert measures to press forward the Bill for securing pensions for Irish Poor-law officers as a matter of right.

◆

Correspondence.

THE MEDICAL REGISTER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In your issue of 22nd December I called attention to the fact that the Registrar of the Irish Branch of the General Medical Council refused to carry out clause 20, of the Medical Act, 1886, viz., registration of the diploma of Membership of the King and Queen's College of Physicians in Ireland and the degree of M.A.O. of the Universities. Since then I have been in communication with the Irish and English Branches, the result of which is that these qualifications are now registrable in England, Ireland, and cotland.

I understand that if applications for registration of the M.K.Q.C.P.I. or M.A.O. be made to the Registrar for Ireland within the next week or ten days, the additional qualifications will appear after the names of those already on the Register in the issue for 1887.

I am, Sir, yours, &c.,

Charles Frederick Knight, M.D.

January 15th, 1887.

◆

THE JACOB TESTIMONIAL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I shall be glad to subscribe to the Jacob testimonial. I know not anyone more worthy of the highest honour, whether by testimonial or otherwise, of the lasting gratitude of all medical men holding public appointments in Ireland, but especially of the Poor-law medical officers; therefore I would honestly say to all, "Palmam qui meruit ferat."

I am, &c.,
G. Bolster.
Woodlawn Cottage, Newcastle West,
Limerick.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—You omitted from my letter that I requested to have my name put down for £1. There were several errata, some of which I would ask permission to correct. Thus onslaughts on their "*entirety*" should have been on their "*interests*." No provincial *students* to be defended should have been provincial *interests*. Old woman's story should have been old "Roman story," so "*exactly*" repeated. In conclusion, let me suggest that the Irish Medical Association should take up the matters referred to in my letter, and that their solicitor should clearly lay down the legal right of all Poor-law medical officers to be deemed to be public vaccinators before the licensing bodies have time to give the newly appointed Dublin gentlemen the monopoly they intend. The Association can thus give a proof of their anxiety to help provincials.

I am, yours, &c.,
T. Laffan.

◆

VITAL STATISTICS OF THE MARRIED AND UNMARRIED.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—It was said by the late Joseph Garnier that the sciences of political economy and hygiene are but of little value unless the majority can be made to take an interest in them. This may serve as an excuse for my bringing the statistics of marriage collected by the late Dr. Bertillon of Paris before the notice of your readers. That very painstaking statistician was of opinion that he had proved that the married state was extremely conducive to longevity, especially to men, and also to women after the age of 25 in France and 40 in Belgium and Holland. His figures are as follows ("Dictionnaire Encyclopédique des Sciences Médicales," Art. Marriage):—From 30 to 35 in France, the mortality of married men being 100, that of bachelors rises to 169, and of widowers to 281. From 35 to 40 the mortality of married men being again 100, that of bachelors is 175 and of widowers 233. From 40 to 45 the proportionate mortality of bachelors and widowers to 100 married men is 174 and 198. Between 45 and 50 the mortality of these classes is 171 and 194; from 50 to 55 the figures are 165 and 172; from 55 to 60 they are 149 and 172; from 60 to 65 they are 141 and 146. Lastly, from 65 to 75 the mortality of married men being 100, that of bachelors is 133 and of widowers 143. The high death rates of widowers are well marked, and the effects of male celibacy on longevity are also very clearly seen in these statistics of Bertillon. A manifest exception to this law which shows, as far as statistics can, the value of marriage to the longevity of males exists between the ages of 18 and 20, when married youths appear to die in far greater numbers than single. The ordinary death-rate of single young men of that age is about 7 per 1,000 annually, but this death rate among young married men of similar age rises to 64 in France, according to Dr. Bertillon, that is, 9 married youths die to 1 single. The same holds good in Belgium and Holland. For this reason Bertillon strenuously contended that young men should not be allowed to contract marriage before the age of 21 at least. From 25 to 30, in France, the mortality of medical men being 100, that of bachelors is 163; but between 20 and 25 it is only 144, and Bertillon thinks that the benefit of the married state for men disappears about the age of 23, and that they should remain single until about that age. With regard to women, Bertillon's statistics show that they are by no means so much benefited by marriage as men are. In France, under 25, married women have a higher mortality than single women, and in Belgium and Holland that higher death rate exists until the age of 40. Doubtless the dangers of childbirth account for this first, and, as families in France are much smaller than in Belgium and in Holland (3 in France and 5 in Belgium, and 5·5 in Ireland), naturally this accounts for the lower mortality of French women. This is an important point in an over-peopled country, as economy and hygiene both point to the evils of large families. In France the mortality of single women between 20 and 25 being 100, it rises to 119 for young wives. In Belgium the similar figures for married women is 157 and in Holland 173. Between 15 and 20 the mortality of maidens being 100, that of young wives is 158 in France and 208 in Holland. It would seem, then, from these statistics of Bertillon, that legislators would do well to discourage marriage in persons of both sexes under the age of their majority, and that the countries like France, where families are kept within bounds, as recommended by Mr. J. S. Mill, the married state is more conducive to the longevity of married women than countries like Holland and Belgium, where families are very large and over-population and low wages abound.

I am, yours, &c.,
C. R. Drysdale, M.D.

Medical News.

Liverpool Medical Institution.—At the annual meeting held on Thursday, January 13th, the following list of officers, council, and microscopical committee was adopted. Those marked (*) did not hold the same office last year:—President: Dr. J. Birkbeck Nevins. Vice-Presidents: Dr. Alexander, Dr. James Barr, *Dr. William Williams, *Dr. R. Robertson. Treasurer: Dr. F. J. Bailey. General Secretary: Dr. A. Bernard. Secretary of Ordinary Meetings: *Mr. Damer Harrisson. Librarian: Mr. R. Williams. Council: Dr. A. Davidson, Dr. Davies, Dr. Robert Gee, Mr. N. K. Marsh, Dr. Wollaston, *Dr. Crawford, *Dr. Grossmann, *Dr. Irvine, *Mr. C. G. Lee, *Dr. Rowe, *Mr. G. E. Walker, *Dr. Whitford. Microscopical Committee: Dr. Alexander, Dr. Barron, Dr. Braidwood, Dr. Briggs, Mr. G. Hamilton, Dr. Hicks, Dr. Logan, Mr. Rushton Parker, Mr. F. T. Paul, Dr. W. Williams, Dr. Wiglesworth. Auditors: Dr. Fleetwood, Dr. Wollaston.

North-Western Association of Medical Officers of Health.—At the monthly meeting of this Society, held at Manchester, under the presidency of Dr. Tatham, of Salford, a paper was read by Dr. Niven, of Oldham, on "The Infectiousness of Pneumonia." He said that evidences were accumulating that pneumonia was ordinarily a febrile disease, having specific contagion communicated to the patient by means of germs, as small-pox and typhus were communicated. Two distinct micro-organisms had recently been discovered in the bodies of infected persons, and these had been isolated and cultivated; and on the products of the cultivation being inoculated in rabbits and mice a malady similar to the human disease had been caused. The bearing of the whole inquiry was that the new view of pneumonia might lead to the preparation of a vaccine having the power to protect anyone inoculated with it against a subsequent attack of this fatal disease.

Odontological Society of Great Britain.—The following gentlemen have been elected office-bearers for the year 1887:—President: Charles S. Tomes, F.R.S. Vice-Presidents (resident):—Henry Sewill, S. J. Hutchinson, J. H. Mummery; (non-resident): Andrew Wilson (Edinburgh), Richard Rogers (Cheltenham), G. C. McAdam (Hereford). Treasurer: James Parkinson. Librarian: Felix Weiss. Curator: Storer Bennett. Editor of the Transactions: Frederick Canton. Honorary Secretaries: R. H. Woodhouse (Council), Willoughby Weiss (Society), C. J. Boyd Wallis (for foreign correspondence). Councillors (resident): Morton A. Smale, Arthur S. Underwood, E. G. Betts, J. F. Corbett, Thomas Arnold Rogers, Sir Edwin Saunders, John Fairbank, David Hepburn, Ashley W. Barrett. (Non-resident): J. R. Brownlie (Glasgow), J. H. Whatford (Eastbourne), F. H. Balkwill (Plymouth), George Brunton (Leeds), E. Apperley (Stroud), J. H. Redman (Brighton).

◆

Notices to Correspondents, Short Letters, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attenion to this rule.

Reading Cases.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

Local Reports and News.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

Dr. Von Nussbaum (Munich).—Clinical paper on "Erysipelas" received.

Dr. G. Ernest Herman (London Hospital).—Clinical Lecture "On the Normal Shape and Position of the Uterus" received.

Dr. J. Milner Fothergill (London).—Paper on "The Neurotic" received.

Dr. Muskett (Sydney).—Paper on "An Unusual Site for Hydatid Cyst, an Addition to the Recognised Varieties of Intrascrotal Disease" received.

Dr. W. H. Pearse (Plymouth).—"Note on Simulating Ulcer of the Stomach" received.

Dr. Martin (Sheffield).—"Clinical Memoranda on Undefined Disease" received.

Mr. Wm. Parker (Bath).—We cannot express an opinion on the conduct of a contemporary in a matter of this kind. The editor probably had some good reason for what he did. We cannot insert the correspondence in our columns, it is not of sufficient interest to the profession.

Mr. Wm. Young (Westminster).—We cannot insert the resolution passed by your society, as it is not founded on fact. It is most untrue "that the heads of the medical profession admit that vaccination is a means of spreading dangerous and incurable diseases." Such statements as these may be the means of gaining subscriptions for your society from an unthinking public, but they will not prejudice those better informed in favour of your veracity.

An Inquirer.—Sir Andrew Clark says that the average amount of fæces ready for discharge in twenty-four hours is about five ounces, and it is known that the amount of solids excreted by the kidneys, under ordinary circumstances, in the average healthy individual, is about two ounces in the twenty-four hours, or four per cent. of the whole urinary product.

M. de Vigal (Paris).—We have no such requirement at present.

Dr. C. E. Sajour (Philadelphia).—Regret we cannot further add to our exchange list. It is alreay too large.

Dr. Randnitz (Prague).—See reply to Dr. Sajour.

F. F. C. (Manchestor) will see the announcement has already been referred to in our last issue.

The One concerned has not enclosed his card. The matter if of much too serious a nature for us to express an opinion without knowing something of the *bonâ fides* of the author. If our correspondent's information is genuine, he will not object to supply the guarantee of his name and address.

THE INTRODUCTION OF THE TERM LAPAROTOMY.

To the Editor of the **Medical Press and Circular.**

Sir,—My friend Dr. Rabagliati, in his clinical paper, "Some Cases involving Laparotomy" (*Med. Press*, Jan. 12th), has conferred upon me a distinction which I do not deserve, in attributing to me the suggestion of this term. I do not know to whom it is to be really attributed, but I certainly have had no share in its introduction. It is a term which I think has no advantages over the one which I generally employ, "Abdominal Section," and as in certain recent papers by American surgeons it has been used in a way which I do not like, and various other suggestions having been made to replace it, personally I prefer to discard it altogether.

I am, Sir, yours, &c.,
Lawson Tait.

7 The Crescent, Birmingham,
Jan. 13th, 1887.

Disappointed.—If you want knowledge, says Ruskin, "You must toil for it; if food you must toil for it; and if pleasure you must toil for it."

Beri-Beri.—We have from time to time given our readers the results of experimental inquiries into this strange disease. We now learn from a Batavian contemporary that Dr. Cornelissen, of the Java Medical Service, has been carrying on a series of investigations in Acheen and Sumatra, with the result that he believes—strange as it may appear—that it is infectious, and also that it is propagated by bacilli. He accordingly recommends a thorough system of disinfection in hospitals and troopships where patients suffering from this malady have been kept. This theory has, as we might readily suppose, not been yet universally accepted by his *confrères* on the spot, though it has caused no little in Java, &c. It deserves, however, being followed up. There may be more in it than meets the eye.

Military Surgeon.—Yes; General Sleeman—whose works we strongly advise you to read, study, and digest—considered that "dry, open sandy plains are healthy sites" for cantonments in India. John Lang hoped ("Wanderings in India," p. 244) "to see sleeping apartments for the married couples, and separate sleeping apartments for the mass of children above seven and eight years of age, libraries, gardens, theatres, &c."

Mr. Owen.—The reference has been crowded out at last moment, it will appear in our next.

◆

Meetings of the Societies.

Thursday, January 20th.

Royal Institution of Great Britain.—At 3 p.m., Prof. A. W. Rücker: Molecular Forces.

Parkes Museum of Hygiene.—At 5 p.m., Mr. M. Ogle Tarbotton: Engineering and Architecture in relation to Sanitary Science.

Harveian Society of London.—At 8 p.m., Annual General Meeting. Election of Officers; President's Address; Conversazione.

Friday, January 21st.

Society of Medical Officers of Health.—At 7 30 p.m., Dr. C. E. Saunders: Legislation for the Purification of Rivers, and its Failure.

Royal Institution of Great Britain.—At 9 p.m., Sir Wm. Thomson: The Probable Origin, the Total Amount, and the Possible Duration of the Sun's Heat.

Vacancies.

Birmingham General Hospital. Jaffray Suburban Branch.—Resident Medical Officer. Salary, £150 per annum, with board, &c.

Newcastle-on-Tyne Dispensary.—Resident Medical Officer (for term of not less than three years). Salary, £250 per annum

London Hospital.—Curator's Assistant. Salary, £1 10s. a week. Apply by letter only to the Warden.

Chelsea Hospital for Women, Fulham Road, S.W.—Assistant Physician (Honorary). Form of application, to be returned by the 31st inst., from the Secretary.

Seamen's Hospital (late "Dreadnought"), Greenwich, S.E.—House Surgeon. Salary, £50 per annum, with board, furnished rooms, and attendance. Applications with testimonials, to the Secretary, on or before the 2.nd inst.

East Suffolk Hospital.—House-Surgeon. Salary, £100 per annum, with board, lodging, and washing. Applications, with testimonials, to the Secretary, on or before the 26th inst.

Worcester General Infirmary.—House-Surgeon. Salary, £100 per annum, with board and residence. Applications, with testimonials, to the Secretary not later than Monday, Feb. 7th.

The Retford Dispensary.—Surgeon. Salary, £120, with rooms, coals, gas, and attendance. Applications, with testimonials, to the Secretary.

Scarboro' Hospital and Dispensary.—House-Surgeon and Acting Secretary. Salary, £80 per annum, with board and lodging. Applications, with testimonials, to the Medical Staff, on or before Jan. 25th.

Flintshire Dispensary.—House-Surgeon. Salary, £100 per annum, &c. Applications, with testimonials, to the Secretary, on or before Jan. 25th.

Appointments

Barr, James, M.D.Glas., Honorary Physician to the Liverpool Northern Hospital.

Bluett, G. M., M.R.C.S., L.R.C.P.Lond., House-Physician to the General Lying-in Hospital, Lambeth.

Branson, J., L.R.C.S., M.R.C P.Ed., Medical Officer for the Laughton District of the Rotherham Union.

Damian, F. G. C., L.R.C.P.Lond., M.R.C.S., House-Surgeon to the Grimsby and District Hospital.

Hopkins, T., M.B., B.Ch.Univ.Dub., House-Surgeon to Sir Patrick Dun's Hospital, Dublin.

Hurlbutt, S., L.R.C.P.Lond., M.R.C.S., Assistant Medical Superintendent of the Fulham Union Infirmary.

Larder, H., M.R.C.S., L.S.A., Medical Superintendent of the Whitechapel Infirmary.

Rowe, A. W., M.S., M.B.Dur., M.R.C.S., Surgeon to the Royal Sea-bathing Infirmary, Margate.

Thomson, D. G., M.D.Ed., Medical Superintendent of the Norfolk County Asylum.

Thornton, B., M.R.C.S., L.R.C.P.Lond., Surgeon to the Royal Sea-bathing Infirmary, Margate.

Marriages.

Hodge—Gedye.—Jan. 14, at the Wesleyan Chapel, Cotham, Bristol, the Rev. Sydney Rupert Hodge, M.R.C.S., L.R.C.P., to Ann Elizabeth, daughter of Francis W. Gedye, of Ashley Grange, Bristol.

Leeds—Edwards.—Jan. 15, at St. Andrew's, Holborn, London, Thomas Leeds, M.R.C.S.Eng., of 2 Staple Inn, London, E.C., to Fannie, daughter of Joseph Edwards, of Burton-on-Trent.

Reid—Horne.—Jan. 5, at the parish church, Kirkcudbright, Wm. Swanston Spence Reid, M.B., C.M., Oakley, Kirkcudbright, to Agnes Darling, daughter of the late James Darling Horne.

Deaths.

Andrew.—Jan. 10, at his residence, St. John's Hill, Shrewsbury, Edward Andrew, M.D., aged 55.

Cæsar.—Jan. 9th, at Tottenham, Charles Augustus Cæsar, L.R.C.P.Ed., L.F.P.S.Glas., aged 41.

Dowell.—Jan. 6th, suddenly, Robert Dowell, M.R.C.S., L.S.A., aged 73.

Clinical Paper
ON
ERYSIPELAS.

(Dermatitis Erysipelatosa, Rose, Rothlauf.)

By Professor VON NUSSBAUM, Munich,
Professor of Surgery in the University of Munich.

Erysipelas, as is well known, is a grave infective disease of the skin. Koch and Fehleisen have succeeded in procuring pure cultivations of the erysipelas cocci, in inoculating them upon nutrient gelatine, and from this back again to the living individual, in whom erysipelas was at once set up. We thus know the microbe, the fungus of this disease; we possess it free from chemical and morphological admixture. By this the newer views regarding erysipelas first gained a firm footing. Now we know with certainty that wherever there is a local focus of disease there must be a small wound, a small ulcer, a tear of the mucous membrane, however small it may be; the cutis or the mucosa somewhere must be the door of entrance for the erysipelas cocci. That a small sore on the mucous membrane of the nose or mouth may escape notice, that the medical attendant frequently does not discover it, is very probable; it is just as much there, however, as in other cases where the purulent cloaca is evident. There are localities, marshy places and hospitals, in which erysipelas frequently appears, especially in the inclement seasons of the year. There are, moreover, people who are especially disposed to it. Red or blond-haired people, with tender white skins, suffer most frequently from it.

Erysipelas is especially prone to attack wounds of the face when they suppurate. The origin is often in the nasal cavity, and the disease mounts upwards through the lachrymal canal to the eyelids and forehead. This superficial form of the disease is most frequently migratory, a so-called *erysipelas migrans*.

Every day it advances a few centimetres farther, when it travels quickly, In the part to which it advances a large swelling is seen.

Often it cannot be said to travel; it is better to say, it daily becomes more extended, as is very distinctly seen in diphtheritic ulcers, especially around tracheotomy wounds.

Erysipelas rarely spreads downwards, but usually upwards, following the lymph courses, or laterally; many times it has crept round the whole body and made the same course a second time.

In erysipelas numerous white blood corpuscles wander out. Red as the skin looks, it is often difficult to procure by puncture with a needle a drop of blood sufficient for microscopical examination.

Various forms are distinguished :—

The *erysipelas œdematosum*, when the minutest drops of exudation are embedded in the cells of the *rete Malpighii*, but where great blisters are present that dry up to yellow crusts; whence are distinguished a *vesiculosum*, *bullosum*, *crustosum*. If an erysipelas remains unadvanced from its place it is called an *erysipelas fixum*.

An habitual erysipelas is often heard of. These are mostly recurring erysipelatous rednesses which are produced by a persistent, permanent cause, as from bad teeth, which only permits short intermissions, constantly giving rise to fresh irritation and exudation in the skin, so that by the repeated thickening a sort of elephantiasis remains.

The diagnosis of erysipelas is generally not difficult. Usually a considerable onset of fever with general ill-health ushers in the attack, or also a sort of shivering chill; then come on redness and swelling, with great tension, some pain on touching the part. The lymph glands around swell in sympathy. A diffuse œdema comes on, which, especially when the connective tissue meshes are large, becomes considerable, as for example in the eyelids, which swell enormously. In the evening the temperature is frequently 40·0—41·5 (104 to 106·7 F.), and the pulse 120—130.

If the mouth participates the epithelium has an offensive odour. Deliriums are often present, even when the meninges are not affected, although they readily are in erysipelas of the hairy scalp, for the disease often spreads from the outer skin to the meninges through the *emissaria Santorini*, and may then cause purulent depositions.

On the hairy scalp the erysipelas is most frequently overlooked, as the doughy swelling under the hair is often the only symptom; brain symptoms then frequently lead to the first discovery of it, and avenge the superficial examination with the surprise of grave cerebral symptoms.

On the third or fourth day acute erysipelas usually reaches its culmination point. The blisters burst, crusts form.

In the more delicate parts of the skin, as around the eyes, abscesses often form, ecchymoses, not unfrequently, even gangrene of the skin, whereby is formed a septic wound, and the high fever takes on an asthenic type. If the erysipelas runs a very grave course it is often to be regarded as only a symptom-in-part of another serious infective disease. Generally from the fifth day improvement takes place. The high fever falls, and the local symptoms lose their condition of active irritation. The skin becomes scaly, pale yellow; losses of substance are, however, replaced slowly.

In regard to prognosis, a dry tongue with much thirst, highly albuminous urine, if lasting only for a short time, are to be looked upon as serious symptoms. If with high fever, inflammatory conditions of the lungs, make their appearance, fatal pulmonary œdema is threatened. Erysipelas also readily attacks neighbouring organs, especially adjacent synovial membranes, which must then pass through an attack of inflammation. The prognosis is particularly bad when just before the attack a great loss of vital fluids has been brought about by serious illness.

Recent times have brought about great changes in treatment. In former ages this infective disease was completely inexplicable to the physician, in consequence of which all sorts of nonsense were perpetrated. Patients would have the disease prayed—charmed away. Then came the time in which bad fluids in the stomach and intestines were looked upon as the cause, and in which unfortunately emetics and purgatives were had recourse to. Only during the last ten years was the right way hit upon, and the surgeon began to destroy or disinfect all foci from which infection was to be feared. Badly smelling teeth and sequestra were removed, the shortest way was opened for the free exit of purulent collections, care was taken that the exit passages of diseased secreting organs were not blocked up, proper attention was paid to fresh air, comfortable rest in bed, the attendant acted withal upon all se- and excretory organs, cooled the hotly glowing, reddened erysipelatous surfaces with cold lead lotion, and sought to set up a barrier against the farther advance of the erysipelas by applications of tr. iodi, turpentine, solutions of arg. nit., or by incision made with the knife, or with the cautery applied to the periphery, and combatted the destructive high temperature by antipyretics, quinine, and later salicylate of soda, antipyrine, thallin, salol, &c.

The endeavours to set a barrier to the advance of the disease have not so far been at all successful, and antipyretics have not effected much. But as it became confirmed through Hueter's incessant endeavours that in every part of the skin when erysipelas was present, cocci were also to be found, and that where there were no cocci, there was also no erysipelas, then it was that the antiseptic method began its successful career. Tar, oil of eucalyptus, turpentine, carbolic acid, boracic ointment were painted upon the erysipelas, foul smelling and diphtheritic openings were swabbed out with strong carbolic acid solutions, but with all these endeavours no result followed in controlling the advance of wandering erysipelas even if the degree of infection was somewhat reduced by the means just mentioned. Only when Hueter undermined the whole superficial area of the erysipelas with a 2 per cent. solution of carbolic acid in water was the disease conquered and advance completely put a stop to. I confirmed the efficacy of this treatment with great joy, for it is a triumph of antisepticism. When following Hueter's example I injected morning and evening a 2 per cent. solution of carbolic acid completely round the margin of the erysipelas, and about a syringeful (a cubic centimetre) to each four or five square centimetres, the erysipelas in every case was arrested.

I had in vain tried all the above-mentioned plans to prevent the spread of the erysipelas. Hueter's method alone had brilliant success, but the procedure was painful, it could almost be called cruel, and consequently found little employment. The method which Kraske recently published, viz., that of scarifying the erysipelas and overlaying with carbolised compresses I have never tried, as I consider it more painful than Hueter's, whilst it does not effect more.

If in accordance with Klebs' proposal 15 to 20 grm. of benzoate of soda are daily given in a mucilaginous solution or in seltzer water, an arrest and fall of the erysipelas are often observed.

In the last few weeks, however, I have had the great joy of successfully arresting and quickly healing the erysipelas in a perfectly painless and easy manner, and that is the reason of my address to-day. I would incite all surgeons to make the experiment that has with me succeeded several times, which may be called a great advance, for erysipelas has hitherto been a true *crux medicorum*.

From all that Unna of Hamburgh has published concerning ichthyol, from all I have myself observed, I must consider this distinguished remedy to be a so-called reducing agent.

Everywhere it reduces the condition of irritation, the superabundant nourishment. Several times I made the following experiment: When erysipelas had attacked a wound, after proper disinfection of the wound, and covering it with a small, fitting, iodoform gauze compress, I painted the whole erysipelas, still spreading in all directions, with ichthyol ointment made of equal parts of ichthyol and vaseline. I then covered the part painted over with 10 per cent. salicylic lint, and fixed it on with a hydrophilous gauze bandage. On the following day I was infinitely joyfully surprised: the erysipelas, the margin of which I had plainly marked out, had not only got no farther, but the surface itself had undergone a favourable change. The red, swollen, shining, succulent skin had become sunken, shrivelled into yellowish-brown creases, the pain also which was felt yesterday on contact had given place to a velvety (pelzig) feeling—in a word, all symptoms of active irritation were, as it were, charmed away and returned no more, although I only used the dressing for three consecutive days. A longer continuance would have been disagreeable to the patient, as the ichthyol on the third day had somewhat affected the skin. I have already had five consecutive cases of erysipelas of the extremities that I have treated with equally surprising results. In erysipelas of the face, perhaps ichthyol collodion suits better, and on the hairy scalp ichthyol soap. Concerning this I have had no experience, for erysipelas has, since we have adhered to strict antiseptics, thank God, become a rare disease. If such a case were not frequently introduced from the town into the hospital we should for a long time have had no opportunity for these new experiments.

As regards the healing power of ichthyol, I must remark that ichthyol is no antiseptic, and decidedly cannot destroy the erysipelas cocci. When it is thus so successful in erysipelas, it seems to me likely that the reducing action of the ichthyol so starves the nutrient soil of the cocci that it is no longer suitable for their multiplication. Many surgeons have thought they have observed an antiseptic action from large doses of ichthyol, I myself consider it to be so small that I do not hold it to be strong enough to destroy the cocci of erysipelas, for they have, as is known, a tolerable tenacity.

I might, in conclusion, say a word regarding inoculation of pure cultivations of erysipelas. This attempt has been made on the covering of fibro-sarcomata, carcinomata, and on the skin of lupus, and in many cases in which the inoculation took and erysipelas was set up, a considerable starving and diminution in size of the affection is said to have taken place. The question comes up naturally, whether the injury and danger set up by the erysipelas are not greater than the advantage, for the first law in the whole art of healing ever remains—*Non nocere!*

◆

THREE CASES OF INSTRUMENTAL MIDWIFERY, WITH REMARKS. (*a*)

By W. MACFIE CAMPBELL, M.R.C.S. Eng., M.D. Ed.,
Consulting Surgeon to the Northern Hospital, Liverpool.

These cases were alike in that dangerous delay, in the first and second stages of labour, and were due to contracted brim antero-posteriorly from prominent sacrum. In the first case delivery was effected by version after long forceps, craniotomy, and craniotripsy had failed, death occurring immediately after delivery. In the second the same manœuvre was successful after craniotomy and evisceration had been attempted; and in the third case, with the experience gained from the other two, version succeeded when the long forceps, although able to rotate the head freely, were unable to bring it into the pelvis.

Case I.—Mrs. D., æt. 31, mother of four children. I had attended Mrs. D. in three previous confinements, of which this is a short record, and I was informed that her first confinement, in which I did not attend, was also instrumental.

Second confinement, fifty-seven hours in labour—forceps.

Third confinement, twelve hours in labour—forceps.

Fourth confinement, twenty-four hours in labour—forceps failed, delivered by version.

(*a*) Read before the Liverpool Medical Institution, December 26, 1886.

Her fifth labour occurred March 10th, 1884, after several days of false pains, which wore her out greatly. At about 3 p.m. I put on the forceps, expecting to be able to deliver at once, but the head would not move; the antero-posterior diameter seemed to be less than on the former occasions, the head itself not being a large one. I obtained the assistance of two friends, who re-applied the forceps and used extractive force without effect, and I then opened and emptied the head and applied the cephalotribe. Still no progress could be made, and the head remaining as high as before, and yet movable laterally. She was losing a good deal of blood, and immediate delivery seemed the only hope. Dr. Howie, whom I had sent for, at this time made his appearance, and after examination suggested turning. Though incredulous as to its possibility, I asked him to operate. This he effected successfully in a few minutes, but the poor woman sank exhausted in an hour. I felt and feel much indebted for the hint given by this proceeding, and in two cases since, which I propose to relate, have succeeded in equally unpromising circumstances.

CASE II.—Mrs. S., primipara, æt. 35, was a strongly made, stout woman, who had been in labour for about twenty-four hours. Owing to narrow brim, the practitioner in charge applied forceps after about twelve hours, expecting to finish at once. In this he was disappointed, and craniotomy was attempted. This failing to dislodge the head, I was asked to help. I found the head in the pelvis open and empty, but on applying the craniotomy forceps could not move the body at all. The blades were pressed into the base of skull and spine, but failed to give any leverage. Evisceration was then proposed and begun, when the state of the patient became very dangerous. I then related my experience of Case I, and offered to make the attempt. It seemed impossible with the ragged skull bones low in the pelvis, but I never turned more easily. The child was soon delivered, and the woman for the time safe, but I was sorry to hear that she sank from blood-poisoning six days later.

CASE III.—Mrs. C., æt. 25, primipara, thirty-two hours in labour. Prominent sacrum was diagnosed early in the case, the os very high up, and notwithstanding very severe pains, no dilatation. The os was soft and dilatable, but during a pain the membranes did not protrude. After twenty-six hours I gave chloroform, and tried to dilate and bring the head down, but had to give it up. Delivery was evidently called for, as the pulse was beginning to run up, and I was not sorry when the friends on the mention of "instruments" desired the advice of one of our leading consultants.

The os was not larger than a crown piece when he examined, and he agreed that forceps should be carefully applied. He kindly gave chloroform, while I applied Barnes' long forceps. When in position traction was begun in the axis of the brim, the left forefinger being used to dilate the cervix. The head would not move, and the more experienced and prolonged exertions of my colleague were also unavailing. The forceps could be rotated and the head put in any diameter, but enter the brim it would not. We retired to consult, and I suggested turning, telling him of the other two cases I have just related. Though incredulous as to its possibility in an empty uterus high up with an undilated os, he approved of the trial, which was successful. The child was nearly lost, and its head was with difficulty piloted hastily through the brim and outlet, where curiously enough most resistance was found. The mother made a good recovery, and the friends flatter themselves the labour was not such a bad one, as it was terminated without "instruments."

Possibly a great deal of harm has been done, and many lives lost by the old teaching that turning should be done after rupturing the membranes. It is certainly easier to introduce the hand while the uterus is full of liquor amnii, but carefully done introduction can be readily effected without maternal injury even with a uterus close upon the child.

Possibly, also, craniotomy has been too much resorted to in the past, and I am glad to notice from late discussions in the papers that its employment is strongly deprecated, turning being the alternative in moderate narrowness of the bony pelvis, while the Cæsarean operation, or Porro's operation, should take its place in extreme cases. Craniotomy involves certain death to the child; abdominal section gives it a good chance, while the maternal mortality has recently been diminishing, and with increased experience and modern modes of treatment is likely to be less. Craniotomy is a serious and unsatisfactory operation for a practitioner to advise, and the certain destruction of life painful to practise, but on the other hand, is probably safer for the mother in hands unaccustomed to operate than the other. We must also remember that it will be a very serious matter for it to be given as the deliberate opinion of the profession that a medical man is to be blamed who chooses the operation with which he is most familiar instead of one which he has perhaps never seen. These may be trite and not altogether original remarks, but are none the less true.

It may not be out of place to say a few words about the use of antiseptics in instrumental deliveries. For examination I use an ointment of carbolic vaseline, 1-20. The forceps are placed in a jug of a hot solution of perchloride of mercury, about 1 to 2 or 3,000, or this solution is used for the hands, followed by the carbolic vaseline for turning. After delivery the vagina, and in some cases the uterus, is washed out with a hot mercury solution, and last of all an iodoform pessary (gr. xv or xx) is left in the vagina. The after daily injection may be either mercurial or of Condy; if the former, the danger of poisoning must not be forgotten. Any after rise of temperature may be met by quinine and opium, or the salicylate of quinine.

NOTES FROM THE
HISTORY OF MEDICINE AND OF MEDICAL OPINION
FROM THE EARLIEST TIMES.

By Surgeon-General C. A. GORDON, M.D., C.B.,
Hon. Physician to H.M. the Queen.

(Continued from p. 46.)

ADVERTING to the general condition of medicine in the fifteenth century, one of the early effects produced by the recent invention of printing was somewhat remarkable. While science as a whole was advanced thereby, medicine, practical at least, lagged behind; idle speculation and theory were retained, while the more accurate induction from facts and experiments were disregarded, except by the few whose names have been mentioned (Meryon, p. 228). Endeavours were made to re establish the rival philosophies of Plato and Aristotle. The former found many advocates in England; the latter in Cisalpine Europe. The most important functions of the body, as well as their disorders, were supposed to result "from the veins." The medical profession was divided into the *revulsionists* and the *derivationists*. The former believed that local diseases originated from a kind of metastasis of the noxious humours from a distant source where they were first formed; the latter, that Nature was apt to set up local congestions towards which the noxious humours flowed (pp. 231-2). Accordingly, the question was discussed by opposing parties whether bleeding should be performed near the part affected or at a distance from it.

The theory was enunciated that disease being a subtraction without any material cause, a knowledge of disease was useless, seeing that a more potent agent, namely, "Natura morborum medicatrix" cures it (p. 342). Another theory of disease, and it expressed by Paracelsus, was that certain entities existed, each of which exerted its influence in a particular manner—the *ens astrorum* on the air, the *ens veneni* on the blood, the *ens naturale* on all other natural things, the *ens spirituale*, and *ens deale* on the siderial body (p. 348). He regarded "tartar" as the principle of all diseases which result from the thickening of the humours, rigidity of the solids, or from the accumulation of calcareous matter; it was attempted in fact to explain the phenomena of the living economy by the laws of chemistry (p. 349).

Systematic chemistry had only been adopted into Europe from the Arabs a short time before this date, and it was asserted that by means of its laws the phenomena not only of inanimate matter, but also of the living body, could be explained. These theories obtained many adherents, and for a time the medical world was divided by the rival doctrines of the Galenists and the Chemists. The practice of the former was described as having been complicated and inert; the theories of the latter as altogether false, and (in 1835) inapplicable. (Bostock, p. 137.)

Among those whose labours aided the advance of Medicine in the sixteenth century was Cælius Aurelianus. He advocated the employment in the treatment of the bite of the *tarantula*, according to the method which he states was introduced in regard to it by Pythagoras. He collected from ancient works on the subject various particulars with regard to hydrophobia, Among other facts he noticed a case of reputed spontaneous occurrence of that disease ("Hamilton's Hist. of Med.," vol. i., p. 399).

James du Bois, otherwise Jacobus Sylvius, in his studies of medicine, applied himself chiefly to the doctrines of Hippocrates and Galen. In anatomy he was the first to detect the existence of valves in the veins. He travelled into various parts of France in pursuit of botany. His scientific qualities, however, seem to have been obscured by his individual characteristics.

Later in the same century Alexander Benedictus related the circumstance that a feather bed was laid aside for seven years on suspicion of infection of plague, yet, at the expiration of that period mischief arose when it was brought into use.

The capture of Constantinople by the Turks at this period led to the removal of much Greek medical literature to Italy. During the latter part of the fifteenth and the first half of the sixteenth century, "the English sweating sickness" prevailed; it broke out in August, 1485, and recurred at intervals till 1551. Syphilis, or venereal disease appeared at Naples, 1492, or at all events was then for the first time described. It is usual to say that this disease was brought by the Spaniards from America; if this be the case the inhabitants of the New World received the more fatal (to them) diseases, small-pox and measles, from the countrymen of Columbus. There is much evidence, however, in support of the position that venereal disease is very much older than what it has been thus represented to be" (Hamilton, vol. i, p. 413).

At the end of the fifteenth and beginning of the sixteenth centuries Marcellus Cumanus clearly describes syphilitic chancres and buboes. At this period Torella was physician to Cæsar Borgia and to Pope Alexander the Sixth. He condemned the extent to which mercurial inunction was carried in the treatment of lues venerea, that inunction having been performed with a preparation known as Saracenic ointment, and commonly used for "a scabies." In moderation mercury was a drug the use of which was obtained and adopted from the Arabians. (Hamilton, vol. i, p. 416.) Another powerful remedy in syphilis, namely, guaiac, was brought from the West Indies by the Spaniards (Freind, vol. ii, p. 361). According to the account given, Gonsalvo Ferrand having become infected with the disease at the siege of Naples, and finding no cure in Italy, went to the West Indies with a view to ascertain how the natives treated themselves in such a case, where the disease was so familiar to them, and as common as the small-pox was in European nations (p. 366). It was shortly after the date in question that the use of China root, or sarsaparilla, in the treatment of syphilis was discovered; and that either Aloysius Lobera, or Frascatorius recommended that in the same disease "the *rubbing in* of the mercury should be continued till salivation comes on well. They also described the method of applying mercurial fumigations, at the same time that they specified the cases in which they ought not to be used" (p. 371). Among other writers on syphilis about the same date James Cataneus and Peter Maynard of Verona, deserve to be specially mentioned.

During the same period a new light was cast upon the treatment of gunshot wounds, as well as wounds in general. American drugs began to be used in British practice.

In 1551 an improved forceps was invented by Alfonso Ferri for the extraction of bullets. Lithotomy by "cutting upon the staff" was introduced. At the same time, surprise was expressed that as the use of the catheter was understood by the ancients, they did not also proceed to the use of the staff in operations for stone instead of continuing that of "cutting upon the gripe." Discussions also arose regarding the comparative advantages of the lateral operation, and that above the pubes. In the same century Jacobus de Carpi wrote on syphilis, both primary and consecutive; on anatomy, and on wounds of the head. Columbus, Eustachius, and Fallopius advanced the knowledge of, as far as was possible without actually discovering, the circulation of the blood (Freind, vol. ii, pp. 365-395).

In the early part of the sixteenth century many of the best and wisest men regarded the heavenly bodies simply as instruments by which the Almighty regulated events. Men of education parcelled out the heavens into six divisions or "houses," and the particular planet which happened to be in any of those "houses," at any particular period of time, they denominated "the lord of the house." To each "house" they assigned a special destiny, much in the same way as Gall and Spurzheim localised our intellectual faculties, moral sentiments, and animal instincts in particular sections of the brain (Meryon, p. 392).

But a spirit of independent research soon animated the medical profession in Western Europe; the purely scholastic system which characterised the Saracenic teaching disappeared before a more discursive literature and polite letters, "humanities," as they were called. The men who achieved the destruction of the one system and the development of the other were denominated "Humanists." They studied the works of Hippocrates in their original text; they knew also the value of correct observation, and of an accurate detail of facts (*Id.*, pp. 278-279). Inasmuch as "the soul is in the blood" thought Servetus, it is necessary to know how the blood is formed; thus was he led to the discovery of the pulmonary circulation (p. 296). And throughout the century the controversy on the subject of revulsion and derivation continued to be a theme of acrid controversy (p. 311).

Against the doctrine of Galen it was shown by John Argentier that the entire bodily system was animated and directed by one vital force; and that different powers of the soul were not inherent in separate portions of the brain as he had supposed (p. 365). While, on the one hand, it was considered dangerous to neglect, without great circumspection, the teachings of the ancients, the Humanists "threw off the despotic yoke of ancient prejudices;" they encouraged investigation and criticism, and protested against dogmatism. The fallacy was shown by John Lange of using the renal secretion as a means of diagnosis, instead of the pulse, upon which Hippocrates and Galen depended (p. 281). And yet, with regard to these diagnostics, Dr. Meryon wrote that Savanarola's work on the pulse and renal secretion, published in 1530, may be read, at the time Dr. Meryon wrote (1861) with great advantage. Many works on uroscopy were written during the period in question (p. 427); a long controversy also took place between the champions of uroscopy and those of the pulse (*Ars Sphygmica*). The notion that gunshot wounds were poisonous was shown to be erroneous; and plastic surgery already practiced for centuries in India, was adopted and improved in Europe by Taliacotius (pp. 431-3).

In the sixteenth century also, arose the three classes of practitioners, namely, the Galenists, or physicians, properly so-called, the Chemists and the Anatomists. The Galenists were for the most part more learned than their adversaries; they consisted chiefly of professors in the universities, and of what may be styled the regular practitioners, who, though strongly attached to the tenets of their great master, carefully observed the phenomena of disease; of their practice, it was described as "complicated and inert." The Chemists paid less regard to mere authority than to observing the phenomena of disease and the effects of remedies; they were diligent collectors of facts, and yet, the actual advance which the practice of medicine received from them "was not very considerable." As science and knowledge gradually advanced, the absurdity of the speculations of the chemists was more generally perceived. Their investigations regarding the chemical constitution of the body, and of the changes induced in it by disease, were not very successful.

The second, or Anatomists, led by Vesalius demonstrated numerous fallacies in the description of parts given by Galen, and accepted on his authority. But in the practice of medicine it does not appear that they affected any direct improvement (Bostock, pp. 145-153).

A section of the medical profession espoused the Platonic superstition of numbers as potential entities in controlling the course of disease. They attributed to the seventh, fourteenth, and twenty-first days the character of turning points or critical periods (Meryon, p. 429). Members of the faculty, accused of administering drugs that were supposed to have done harm, were, in 1595, liable to be severely dealt with by their colleges (*id.*, p 458).

That then, as in times much nearer our own day, a very striking difference existed between the tenets held or professed by the scientific physician and the practical man, the mere "curer of disease," or the empiric, is rendered evident by circumstances connected with that period, the record of which has come down to us. It is related, for example, that Sir Robert Talbot, a celebrated empiric, was asked the question by an "orthodox," otherwise, scientific physician, "What is fever?" The reply of the "empiric" was, "a disease which I cannot define but can cure, and which you cannot cure, but can define." (Meryon, p. 74). The reported anecdote is commended to the attention of those physicians of the present day who talk largely about the nature and causation of certain forms of fever, but among whose patients the rate of mortality is something to take note of.

In the seventeenth century a theory of medicine arose, based upon the hypothetical *archæus* of Paracelsus. This *archæus* represented an immaterial force directing and controlling all the bodily functions, and educing all things from water by a species of fermentation. The water in the earth, according to this theory, represented the blood in animal bodies. From this "fermentation" in the body arose "gas," otherwise the *aura vitalis* (Meryon, p. 378). Frascator revived the theory of atoms of Democritus; he represented those atoms as demons, and the demons an emanations from the Deity (p. 383).

In reference to these and some allied theories, Meryon, writing in 1861, observes that, we are daily reminded to what excesses belief may be carried, even when the judgment is intrenched behind the defences which modern science supplies (p. 398).

The theory of self-generated *poisons* was expressed by Zacchias. He limited his belief in them, however, to the corrupt humors secreted from wounds. He considered the specific symptoms as following the ingestion of poisons; and discussed the question of inborn poisons (p. 412). It was also suggested that one poison might expel another (p. 414). In connection with the occurrence of plagues, it was observed that such outbreaks took place mostly, if not always, in conjunction with "some local and adequate cause," as some local corruption of the air (p. 419). Pathological anatomy came to be attentively studied (p. 425). At this period Harvey wrote that: "The doctrines inculcated on the subject of the humors, and which, as being entertained by the ancients, Fabricius regards as certain truths requiring no further proofs, are inconsistent and false." (Dr. Russell Reynold's Harveian Oration, 1884.) And yet, now, late in the nineteenth century, those very doctrines are revived.

During the seventeenth century, also, the advocates of chemistry in relation to physiology, referred the states of health and of disease to certain fermentations, which were said to take place in the blood or other fluids; these fluids were themselves believed to be the result of specific fermentations, by which they are elaborated from the elements of which the body is composed. [What is that theory if it be not the "germ" of the more recent speculations to which the name has been given of "the Zymotic Theory of Disease?"] Certain humors were supposed to be naturally acid, others naturally alkaline; certain specific diseases were the result in either case, the remedies for which were to be the opposite of their supposed cause (Bostock, p. 157).

It has been remarked, however, of the Iatro-physical school of the seventeenth century, that "the more judicious of its followers refrained. as a *judicious modern phyiologist does*, from too immediate an application of their principles to daily practice (Encyc. Brit., Art. Medicine).

Another theory of disease was that morbid action consisted in an effort of nature to remove some morbid or noxious cause (Bostock, p. 161); while the method observed by Sydenham was not to manifest an undue attachment to any theory, but to devote himself to the study of disease, and the effects of remedies upon it—in other words, to clinical experience (p. 162). He described disease as "an effort of Nature to restore the health of the patient by means of the elimination of the morbific matter. His principles were welcomed as a return to Nature, by those who were weary of theoretical disputes. He described many diseases as being specific in their character and not due merely to an alteration in the primary qualities, or "humors" of the older schools (Encyc. Brit.). Mankind at the time were not aware of the importance of observation and experience (Bostock, p. 163).

The next theory expressed was that of the "mathematical" physicians or Iatro-mathematical school. According to that theory, every part of the body is under the influence of gravity and mechanical impulse; all the vital functions may be explained by the principles of hydrostatics and hydraulics (p. 165). Mathematical theories of fevers and of the actions of poisons were published (Encyc. Brit.). As the mathematicians gained acceptance, the theories of the chemists lost ground (Bostock, p. 165).

Meantime, the sect of Vitalists was gradually rising, much on the lines laid down by Paracelsus. It was observed that the action of the mind over the body could not be referred either to a mere chemical or to a mathematical agent; all the actions of the body were accordingly held to be under the control of the "anima," which in many respects resembled the "archæus" already mentioned (*id.*, p. 170). The theory so-called was introduced by Stahl, in substitution of the mechanical conceptions which at the time prevailed. According to its tenets the ordinary animal life in man was attributed to the soul, while the life of other animals was left to mechanical laws. His object was to oppose materialism (Encyc. Brit.). Many of the actions which Stahl referred to the "anima," Hoffman ascribed to the "nervous influence." He desired to reconcile the opposing "spiritual" and "materialistic" views of Nature. His theory of disease rested upon "a complete theory of the universe." Although he considered that the fluids were occasionally the primary seat of disease, he conceived that in most cases the solids were so (p. 180);—a theory supposed to have been borrowed from that of "constricted, and relaxed fibre" of the ancients (p. 182), and pre-indicating that of "arterial tension" of to-day. The humoral doctrine which, under different names, had hitherto prevailed, was now systematically opposed; that of "solidism" was advocated in place of it (p. 185).

In the seventeenth century, and also in the eighteenth, the tendency of the Anatomists was, without any regard to Nature or to right philosophy, to advance every trifling discovery into an hypothesis. Hence, those idle dreams about the nervous, the pancreatic juice, the bile, the saliva. They explained one thing connected with the human body by the Aristotelian, another by the Cartesian, a third by the Chemical, and a fourth by the Mechanical principles. The latter class argued that "since the human body is nothing else but a fine contexture of solids and fluids, which observe the rules of mechanism, it is amazing to find that men should think of any other principles than the mechanical to explain it by" (Freind, vol. ii, p. 398). It is asked—would any one account for the motions of a watch from the doctrine of acid and alkali? (*id.*) And so on. Very much indeed like the language employed by a certain class of "scientists" of the times in which we live.

Clinical Records.

ST. BARTHOLOMEW'S HOSPITAL.

Case of Hydrophobia.

Under the care of Dr. Southey.

Charles B., æt. 15, a messenger, was admitted into "Casualty" Ward on July 15th. Highly nervous temperament, dark complexion. Had not suffered from any previous illness, save measles and whooping-cough when young. He was bitten by a dog five weeks previously, June 11th, in four parts of the first phalanx of the right forefinger. The wounds were cauterised the same evening, and his mother says they were healed in about three weeks.

From the time of the bite up to July 13th his mother noticed no change in his health. He did not suffer from headache, nausea, vomiting, anorexia, or vertigo; the senses of light, of taste, of hearing, and of smell, were not affected; he walked steadily, and he was not excited beyond his wont; his sole complaint was of an itching in the wounds during the time of their healing; the itching was confined to the wounds and so greatly did this disturb him that his mother had to remonstrate greatly with him to prevent him from scratching them.

On July 13th his appetite suddenly became impaired, though he had taken well of food the previous day; he took but little at breakfast, dinner, or tea (at 5 p.m.). At 7 p.m. he experienced a severe jumping pain in the right upper extremity; it seemed, he said, to originate in the right shoulder, and to shoot down all round the arm into each finger. He took also but little supper, only a crust of bread and a glass of beer, and he was sick soon afterwards on his way to bed. The pain in the right upper extremity subsided somewhat and became confined to the right shoulder. He did not suffer from headache or from recurrence of vomiting and he had a good night's rest.

On the following day, July 14th, he awoke feeling well, free of pain; he took a moderate breakfast and he went out feeling well. About noon he felt precisely the same sort of pain as he had experienced the day before; the pain remained of the same character through the day; patient said it jumped about three times per minute into the forearm and finger; and that the pain seemed to be almost constant in the right shoulder and arm, and only at intervals to shoot into the forearm and hand, and that he did not notice it when he was in any way excited.

Next day, the 15th, he drank freely, but ate nothing at breakfast. About 1 p.m., on attempting to swallow, he had some spasm, and according to his mother's statement, some difficulty in swallowing. About 3 p.m he felt unsteady in his gait, trembled somewhat, but did not feel as if he would fall. About 5 p.m. he was admitted into St. Bartholomew's Hospital. At the time of admission he was quite rational, spoke readily and correctly in answer to questions, walked to his bed down stairs fairly steadily, and took off his clothes with but little assistance. He stared wildly, the eyes were widely open, the pupils were dilated and freely reacted to light, undergoing indeed continuous change of shape. The tongue was dry, the skin dry and somewhat hot, the temperature 102·4 in the axilla. The pulse was full, strong, regular. It was 96 per minute and of good tone. The respirations were of varied frequency, from 22 to 40 per minute. The lungs seemed healthy. The heart's action was somewhat quick and vigorous, but no abnormal sounds were detected. Neither the area of hepatic nor of splenic dulness was enlarged, and there was no enlargement of the glands of the neck or groins. The right axillary glands were slightly enlarged. When he got into bed he lay quietly, and he answered questions quite rationally, and said he felt comfortable. The wounds were cicatrised, and the cicatrices looked healthy. At 6 p.m., while lying quietly, he was suddenly seized with short, hurried, gasping, respirations, and increased anxiety of expression; he felt, he said, as if he should be suffocated, and he ascribed his feeling to thick phlegm in his throat. This was the first attack of its kind, his mother said, and it quickly passed off. The attacks now recurred about every seven minutes. At 7 p.m. he passed water, sp. g. 1025, trace of albumen, no casts nor red blood cells. About 8 p.m. the attacks became more frequent. At each attack he jerked himself in a sitting posture, when he was relieved (in about eight seconds). He was quite rational, and repeatedly said how painful it was to be struck down with such shortness of breath. He said he could not drink, but he made an attempt to do so on request. He sat up with a determined look, took the feeder in his two hands and then with a sudden movement put it to his mouth, took some milk, then almost threw the feeder to the nurse, though careful that she should take it; at the same time he seemed to swallow, and threw himself at full length on his bed, giving the idea of intense relief. He now had a vapour bath, during which he complained greatly of the heat, and he perspired freely. An attempt was made to pass a catheter through the nose, but the slightest touch evoked such violent spasms that the attempt was relinquished. After some persuasion, however, the patient was prevailed upon to make the attempt for himself; he passed the catheter with his two hands little by little and by jerks, and immediately after passing it a little further he jerked his hands from the catheter, sitting all the time upright, and his body and extremities shook violently, while the expression of his face became wild, and his eyes staring. He finally passed the catheter, and potassium bromide gr. xv with chloral hydrate gr. x were administered. The pain in the right upper extremity remained as it was the day before

At 10 p.m. he again attempted to pass the catheter for himself, but the moment he put it to his nose he threw back his head and held out the catheter at arm's length, while he gasped for breath, and his arms and legs were violently agitated with short rapid spasmodic movements. Then with determined air and sitting upright, he made further attempts, and after a few trials succeeded in introducing the catheter just within the nostril, and immediately his arms and legs became again violently agitated as before, and he gasped for breath. He finally introduced the whole length of the catheter about an inch at a time, and he was fed through it with milk, one pint; brandy, two ounces; pancreatin, ʒss. In addition, potassium bromide, gr. xv, chloral hydrate, gr. x, pilocarpin nitrate, gr. 1-10th were administered with the food. Soon afterwards he perspired, freely. During the night the above-mentioned fits recurred at shorter intervals, and each time he "hawked" violently.

Next morning (July 16th) about 6 o'clock the fits recurred at about intervals of one minute, and he hawked violently, and spat with great force, violently throwing back his head each time that he spat. His pupils were widely dilated, and the conjunctiva were bared all round each cornea. The eyes were very sensitive to light; and the light of a candle sent him into violent spasms. He talked quite rationally, and complained of an itching on the right arm when it was gently stroked, but he had no pain in the arm. While hawking he apparently retched violently, but was unable to vomit. He hawked up apparently only phlegm from the throat. Ice was given to him to suck, but it did not relieve his throat very much. An ice-bag also was applied to the stomach, and the patient held it there himself. It relieved the retching somewhat. The pulse now intermitted about every eleventh beat, and the respirations were irregular in frequency, during a fit the pulse was quickened, to 108 or 120.

8 a.m.—Absolutely refused the vapour bath, saying that he would not have that man with his machine, and asserting that the "machine" had a bad smell.

11 a.m.—He again passed the nose-catheter after much persuasion, and while passing it the fits of spasm were much more violent than they had been, and he called for a chamber utensil two or three times in an agitated manner, and passed a little water each time in a short quick stream. After passing it he was fed with milk, half-a-pint, brandy, ℥ss, mutton, ʒij, pancreatin, ʒss, pilocarpin nitrate, gr. 1-20th, chloral hydrate, gr. x, and potassium bromide, gr. xv. He soon perspired freely, and the paroxysms were less frequent and severe. But about noon he became again very restless, he got up, stood on his feet, and said he would throw himself into the Thames; he still recognised each of us, and was tolerably rational, and said he should be dead in four days, that it would be all over then, but he showed no fear of death, never mentioning the bite. He asked repeatedly if he might go with his mother to the cemetery and talked of his grave.

4 p.m.—The fits recurred still more frequently, he hawked and retched still more violently, bringing up, however, only phlegm. He now experienced great anxiety about his mother, kept getting up and out of bed and he resisted greatly the attempts to put him into bed. The bowels were freely opened, and he passed water freely. He could not pass the catheter, the slightest touch of it causing the most violent spasms. With great difficulty he was induced to get into bed, and then was put slightly under the influence of chloroform and was fed with milk, half a-pint, brandy, ℥ij, eggs, ij, pancreatine, ʒss.; also pilocarpin gr. ⅓rd, chloral hydrate, gr. x, and potassium bromide, gr. xlv, but being sick under the influence of the chloroform he rejected about one-third of this mixture, though he was apparently wholly unable to vomit prior to the administration of chloroform. While regaining consciousness he was forcibly impressed wtth the idea that he had been sat upon by a "gang of medical students," and the idea remained on his mind more or less till death.

6 p.m.—The fits continued, and the noise was not a hawk so much as a bark. Pulse becoming very weak, and he perspired freely.

9 p.m.—Attempts were made to induce him to pass the catheter, but it was of no avail. Shortly after he asked for bread and butter and ate it and drank some.coffee with a spoon. He swallowed easily without the slightest spasm.

12 p.m.—Attempted to induce him to pass catheter, but it was of no use. Gave him a little chloroform (he asked for it) by inhalation and fed him with milk Oss, brandy, ʒij, eggs, ij, pancreatin, ʒss, pilocarpin, gr ⅓rd, chloral hydrate, gr. x, potassium bromide, gr. xlv, of which he retained about two-thirds. As soon as the chloroform took effect he was almost immediately sick. After this he lay very quietly on his back, talking incessantly and hawking, but having no spasm, and perspiring freely.

17th, 1 a.m.—Vomiting at intervals a dark matter, hawked to the last; vomiting became incessant until 5 a.m.

2 a.m.—Imagined himself an engine, wishing to be unhooked from the back of the train, also imagined himself a porter, and injured by carrying heavy weights. Continued to say that he had been ill-treated at Gray's Inn Road, and declared he should go mad if any one knew.

4.30 a m.—Thought he had been reading his bible for three days. Anxious to go home to tell his mother that he had given up swearing and requesting that we should not tell any one else. Thought he was on board ship, and received many bullet wounds. Wished us to tell his mother that the wounds were the cause of his illness. Thought his mother mad in an asylum; says he has a cousin in an asylum; asked if his cut on his finger was the cause of his mother's madness.

5.30 a.m.—Had a severe spasm.

5.45 a.m.—Another severe spasm. The slightest touch caused spasm; when his ear was touched, indeed, even when the patient touched it himself, he had spasm and violently flung himself away from the finger that touched him. Sat up and took the vessel and hawked; then he fell back utterly collapsed and profusely perspiring and vomiting, he died in about five minutes.

Post-mortem Examination, made by Dr. Moore, on July 18th, (copied). *Body.*—Well nourished. Rigor mortis well marked; on the index finger of the right hand were two scars; both were livid; dependent parts purple. *Head.*—Calvaria—meninges, normal. A larger quantity of clearer fluid than normal in the lateral ventricles. *Chest.*—Heart contained firm blood clots. Endocardium and pericardium normal. *Lungs* contained much blood, otherwise normal. No adhesions between the pleura; larynx, trachea, œsophagus and bronchial glands, normal. *Abdomen.*—Liver normal; ducts, free; spleen, kidneys, and ureters, normal; bladder contracted and empty; stomach and intestines normal. *Back.*—Vertebræ, cord, and meninges, normal.

◆

Transactions of Societies.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

A meeting of this Society was held in the Hall of the Royal College of Surgeons of Edinburgh on the 19th January,

Professor **Grainger Stewart** in the chair.

ON REMOVAL OF THE UTERINE APPENDAGES.

Mr. **Skene Keith** showed interesting specimens of diseased ovaries and Fallopian tubes, removed by operation, and thereafter read a paper on "The Removal of the Uterine Appendages," in which he detailed the results of his own and Dr. Thomas Keith's operations in this department. Mr. Keith expressed the opinion that the commonest cause of disease in these organs is laceration of the cervix. He thought that if greater attention were paid to the primary lesions, there would be less necessity for operative interference later. Removal of the appendages had, without doubt, been resorted to too frequently. He did not think that gonorrhœa was a frequent cause, at least not so far as the cases which came to him were concerned. In reply to Professor Annandale, Mr. Keith said he did not think inflammatory affections of the parotid were commoner after uterine and ovarian operations than after other operations. He had not met with a case of suppuration of the parotid.

Dr. **Brewis**, Mr. **Cathcart**, and Dr. **James Ritchie** also took part in the discussion.

Professor **Annandale** read a paper on

PRELIMINARY TRACHEOTOMY.

He advocated the performance of tracheotomy as a preliminary step in all operations about the oral cavity. It should be done immediately before the major operation. The risks of complication were greater if an interval were allowed to occur. Various instruments had been arranged in order to the more perfect carrying out of the objects. Trendelenburg's instrument embodied the principle well, but he thought it cumbersome and liable to go wrong. He was a great believer in simplicity of instruments. He made use of a slightly modified vulcanite tracheotomy tube, with india-rubber tubing attached. The tracheotomy tube was fixed in position by means of thread and gutta-percha, and the india-rubber tubing was led away from the patient, out of the way of the operator, to a tumbler containing a pad of wadding soaked with the anæsthetic. The upper part of the œsophagus was plugged with a long pad of cotton-wadding rolled in oilcloth, with thread attached, so that it might be withdrawn at any time. This he thought an additional advantage, as blood passing down into the stomach doubtless kept up the tendency to sickness.

Mr. **Duncan** agreed with Mr. Annandale as to the advisability of preliminary tracheotomy immediately prior to the major operation. He thought the simpler the expedients made use of the better, and he expressed the opinion that that method was the best for each operator which his own experience had led him to adopt.

Dr. **Alexander Bruce** showed the brain of a child who had died in the Sick Children's Hospital with marked convulsive symptoms. The little patient had been under the care of Dr. Carmichael, who used to demonstrate it to his class as a typical case of simple meningitis recovering. Some weeks after being discharged it returned again to hospital, and died in convulsion. The membranes were found to be natural, except at the base posteriorly, where there was a little thickening of the pia mater and a glueing together of two adjacent points in the cerebellar hemispheres. The lateral ventricles were greatly distended with fluid, as also the third ventricle and the *iter a tertio*. The veins of Galen were not distended. Dr. Bruce thought the distension of the ventricles was due to the old meningitis.

ACADEMY OF MEDICINE IN IRELAND.

Surgical Section.

Meeting held Friday, Dec. 10, 1886.
The President, Sir Wm. Stokes, M.D., in the Chair.

CONSERVATIVE SURGERY IN DISEASES OF THE FOOT AND ANKLE-JOINT.

Mr. Wheeler read a paper on conservative surgery in disease of the foot and ankle-joint, of which the following is an abstract:—

Having briefly alluded to the anatomical distribution of the synovial membrane and to the arches of the foot, he recorded several interesting and successful operations, including excision of the os calcis, of the astragalus, scaphoid, cuboid, middle, cuneiform, and metatarsal bones; also resection of the first phalango-metatarsal articulation. The last case he recorded was excision of the os calcis, astragalus, and the malleoli, together with the articular surface of the tibia. He decribed in detail the diseases requring excision of the os calcis, the form of incision, and, after treatment, he condemned the subperiosteal operation in such cases. All his excisions of the os calcis were successful, and the locomotion of the patients but little impaired. One of the cases he operated on died seven years after the operation from phthisis. The case of excision of the astragalus had been seen within a very recent period, the lady had a movable joint between the os calcis and malleoli, and possessed nearly equal powers in the foot operated on and in that unoperated on. The case in which he removed the astragalus, os calcis, and the malleoli, with articular surface of the tibia, for disease of these bones, the patient had been treated in India, and afterwards in London, where he was told that there was not any disease of the bone, and that he would be recovered in two months. This gentleman had left for India last October, at which time he was able to wear a well-adapted boot and walk with the aid of a stick. A letter had been received from him on the 1st of November stating that his powers of locomotion had improved. A cast of the foot after operation and recovery was shown at the meeting. Mr. Wheeler concluded his communication by emphasising the necessity for carefulness in diagnosing the seat and cause of disease of the foot, likewise the stage the disease was in before undertaking partial operations.

The **President** congratulated Mr. Wheeler on his unbroken series of successes, but this did not tally with the experience of most operating surgeons, including his own. He had not found cases in which the disease was sufficiently limited to insure satisfactory and permanent results by partial excision, and the want of such limitation was the chief reason why Pirogoff's operation was abandoued. Indeed, he was himself one of the first, if not the first, in this country to perform excision of the ankle-joint for caries, and he obtained what seemed to be a successful result—the wound healed and the patient had the use of his foot for two years; but at the end of that period the disease manifested itself again, and contemporaneously with it there was also evidence of tubercular disease of the lungs, which prevented further operative measures. In caries of the tarsus, he would in the majority of cases, be disposed to perform Symes' amputation at once, having regard to the liability of a recurrence of the disease in the bones which at the time of operation are apparently healthy. He concurred with Mr, Wheeler in his remarks on Chopart's operation, that contraction did not follow. But Mr. Wheeler seemed inclined to disparage the subperiosteal method, without giving definite reasons. While the advantage of some excisions by that method were exaggerated, as in excisions of the elbow-joint, yet in others there was no doubt that it was useful, especially in the shoulder-joint, and the excision of shafts of bone, as the fibula, radius, and ulna: for in the young the preservation of the periosteum was of great importance. In excision of the elbow he did not think that better results were obtained by this than by the older method.

Mr. **Croly** said that if there was one subject more interesting than another to him it was preservative surgery, especially that of the foot. He had had his first lesson in it from the late Mr. Tufnell in the treatment of a girl for disease of the cuneiform bones. At the time Mr. Tufnell was in the habit of doing Symes' amputation, but in this case he resolved on gouging out the cuneiform bones and leaving a foot which would enable the girl to earn her bread. Having since performed a great number of operations for disease of the ankle-joint, himself, the result was that he did not like the operation for incision of the os calcis. He had not had success in saving the foot where the disease seemed to be confined to the os calcis. He removed the os calcis by a horse-shoe incision where the rest of the bones seemed sound, but it turned out that they were infiltrated. He had had, however, a most successful case in private practice of excision of the calcis for gunshot injury where the bone was shattered and shot lodged in the calcis, and the gentleman now had a useful foot. He had met another case of great interest. A man fell off a horse injuring his ankle-joint, which exhibited all the evidence of compound fracture. Amputation was proposed, but the man refused to allow it. Months afterwards, when under his care, he cut down under the ankle-joint and found the astragalus was detached and that the tibia had come down and accommodated itself on the os calcis. The man was now engaged as a coachman and groom with a useful foot. With regard to the utility of potassa cum calce, a boy was brought into hospital with what seemed to be an incurable foot and a fit case for Symes' operation; but determining to give the child every chance, he bored the cuneiform bones with potassa cum calce, and the child left the hospital with a useful foot. The advantage of saving the periosteum of the calcis bore no comparison to that of saving the periosteum of the shaft of the bones. He did not think he would try to save the periosteum of the calcis, as he would not expect a good result; and so, too, as to excision of the ankle-joint for disease, accident cases excepted. He would also be sorry to remove the foot by Symes' method, without giving a chance of saving it.

The **President** explained that he did not advocate a rush for amputation knives in all cases of caries of the tarsus, but only in those where the surgeon has to determine between extensive gouging of the tarsal bones and their removal, did he prefer Symes' method.

Mr. **Croly** said his own experience told him that the foot was a part of the body for which a good deal could be done in the way of preservative surgery. It was hard to tell where to begin, seeing that the surgeon sometimes found the cartilage sound and a bad bone under it, and *vice versa*.

Mr. **Barton** distinguished between caries from disease of the bone and that from accident, which was approached by the surgeon on different lines. The experience of the practical surgeon was unfavourable to gouging or partial operations where there was extensive caries or the disease was diffused. Hutton, who had operated as Mr. Wheeler did, discountenanced the then new procedure as leading to an unsatisfactory result, and yet Mr. Wheeler, by removing a similar amount of bone without following the same line of incision, had obtained success. He himself struggled to save a foot of which the disease was only partial, and his experience was that while he had been successful in some cases, yet in a great many he had been unsuccessful, and it would have been better for the patients had he performed Symes' operation at first.

Mr. **Croly** asked was Symes' amputation preservative surgery.

Dr. **Doyle** said it seemed to him, without pretending to be a pathologist, that the specimen of bones marked "Dec. 17, '85," in the case of the patient who refused to be operated on in London, did not exhibit much disease. He would like to have the opinion of a pathologist on the point.

Mr. **Franks**, while sensible of the fact that the more the patient had of his own feet to walk upon the better, observed that under Symes' amputation feet and boots might be applied which would allow of the patient getting about well. The unsatisfactory results of the partial excision were due in the first instance, to foci of disease being left untouched, and secondly, to operating on patients who had sunk so low in health that they had no recuperative power in them. At the same time, the condition of the patient was often made too much of in these days of antiseptic surgery, and therefore conservative surgery might be adopted with more hope than before. In tubercular disease, however, health was a great factor, everything depended on the constitution of the patient, and caries sometimes got well without operation at all. The tendency of surgery was to partial excisions, especially in view of the success achieved by Ollier, of Lyons, who was a great advocate for subperiosteal operations. It was obviously better to leave a periosteum that could develop bone rather than excise it with the bone and hope for a pad of cicatricial tissue to walk upon. He witnessed a case of a girl of eighteen or nineteen years of age which impressed him with the power of the periosteum in forming bone. Mr. Bryant had by a long excision excised the head of the thigh bone and three-fourths of the shaft, leaving the periosteum. This bone was standing by the patient's bedside. On examining the girl he found that the head and neck of the femur had reformed, and also three-fourths of the shaft, every movement of the hip-joint being perfect. In partial excisions of the foot, he did not see why such operations should be attended with success in France and Germany and not in Ireland.

Mr. M'Ardle, looking at Mr. Wheeler's successes, said the prospects of preservative surgery were bright, but his own experience and reading pointed to a different conclusion, even with the German surgeons, and therefore he inquired whether Mr. Wheeler had given all his cases, since if he had not, the omission of his failures would be unfair to the Academy.

Mr. Henry FitzGibbon having assisted Mr. Wheeler at the operation for the excision in the case of the Indian planter, testified to the fact that the bones were extensively diseased, including the os calcis. It was in that case a question whether there should be a Symes' amputation or excision of the os calcis. For his own part, he thought amputation would have been the better surgery, and therefore he was agreeably surprised to see the man walking well with the assistance of a stick before he left Ireland—a far better result for a man whose avocation necessitated horse exercise than could be acquired with an artificial foot. In considering the question of excision, the main point was what was the primary cause of disease in the bones. The great distinction was between disease of bones resulting from accident and disease arising from constitutional cachexia. He had had a case himself of a girl who dropped a needle into the middle cuneiform bone, which he excised, and she made a perfect recovery. She had 32 sound teeth—a good indication of the absence of constitutional cachexia, and this was the case also with the Indian planter.

Mr. Wheeler, in reply, said he did not agree with the President in thinking that in advanced disease of the tarsus amputation by Symes' method was the correct surgery to adopt. It might have been that the President's want of success in partial excisions of bones of the foot was due to his allowing the disease to advance beyond the limits of partial operations, or his cases might not been either in the stage or situation from which it would be reasonable to anticipate success from partial excision, and that resection of the cuboid bone or os calcis would have been more likely to succeed than resection of the middle cuneiform, even for anatomical reasons. Resection in disease following injury promised more favourably than resection for disease from constitutional causes; and likewise in disease of bones following inflammation of the ligaments than when the disease originated in the bones. As regards subperiosteal resection, he thought that in resection of the os calcis it was not advisable, no more than in resection of the elbow-joint for caries. Preserving the periosteum in resection of long bones was not analogous, but even in such cases he believed the periosteum was diseased and did not after the operation carry on the functions ascribed to it. The President's experience of Chopart's operation was similar to his own. Examination proved that not only was the tendo-Achilles engaged but also the flexor communis and pollicis longus muscles, and it was his custom not to relax these muscles but to extend them by keeping the ankle-joint flexed to the leg extended. If, on the contrary, the leg was kept flexed it would shorten there tendons during the healing process and favour contraction. He concurred with Mr. Barton that disease of the foot in the diffuse and progressive stages was not suitable for partial excisions, but he disapproved of gouging as tending to excite inflammation and further disease. In reference to Dr. Doyle's remarks, he had only to say there was not any difficulty in observing the disease in the bones exhibited. All his cases were communicated to the Academy exactly as they occurred, and their remarkable success excused the inquiry to that effect. One of the four cases in which he excised the os calcis died four years after the operation of phthisis.

The Section then adjourned,

LIVERPOOL MEDICAL INSTITUTION.

The Sixth Ordinary Meeting was held on December 23rd, 1886.

The President, Dr. Nevins, in the Chair.

The following pathological specimens were shown:—

Perforation of bowel from a case of typhoid fever, by Dr. Robertson; ulcer of the vermiform appendix, by Dr. Barron, in which there was also thrombosis of the portal vein and absence of bile, but no ascites; and cystic degeneration of kidneys, evidently congenital, by Dr. MacAlister, in which the kidney was almost entirely composed of cysts.

Dr. W. Macfie Campbell then brought forward three interesting and suggestive

CASES OF INSTRUMENTAL MIDWIFERY,

which will be found at page 68.

In the discussion which followed,

Dr. Steele said this practice was taught by Barnes. In every case of difficulty with the forceps he had been in the habit of turning. He had never performed craniotomy, but had turned successfully where craniotomy had been adopted at a previous confinement.

Dr. Bailey suggested that premature labour should be brought on when difficulty was known to exist.

Dr. Pooley had had forty years' practice in New York, and he expressed a hope that the time was coming, as he believed it would come, when craniotomy would be completely replaced by Cæsarean section. By all means bring on premature labour.

The President said that Dr. Pooley's suggestion was one of very grave importance. He himself dreaded the general introduction of Cæsarean section.

Dr. Stuart also spoke.

Mr. Richard Williams showed a case of

DIVERGENT SQUINT,

operated on in accordance with a novel method, which he described, and the distinctive features of which are that the conjunctiva and tendon are held together in a single loop of ligature, and that the latter passes through the tendon from edge to edge, instead of from within outwards as in the ordinary method. The case itself was interesting in that both eyes were hypermetropic, and equally so (Q. D), and that vision was quite normal in each. The patient, however, had lost the power of conjugate action. This was completely restored by the operation, and the case was satisfactory in every way.

Mr. C. G. Lee said that, in assisting Mr. Williams in operating on one of the patients referred to, two things particularly struck him: 1. The celerity with which the operation was performed; and 2. The simplicity of the operation. In fact, by Mr. Williams's method, reposition of the internal rectal muscle had been entirely altered from being one of the most troublesome operations that an ophthalmic surgeon had to encounter, to one of the most simple. One great advantage of Mr. Williams's method was that only one suture was needed, thus obviating the very usual confusion that arises when several fine threads get mixed up in a small wound; again the necessity for employing those ingenious strabismus hooks, resembling a lithotrite, which were introduced for holding up the severed tendon, was quite done away with.

Mr. Bickerton also spoke.

Dr. J. Wiglesworth read a paper on

THE DIAGNOSIS OF SOME ABERRANT FORCES OF GENERAL PARALYSIS OF THE INSANE.

The typical forms of the disease were excluded from consideration, because whether the mental degeneration was characterised by gay delirium or progressive dementia, no difficulty in diagnosis was experienced, so long as the motor troubles were distinctly marked. The three chief aberrant types that the disease might assume were: 1. Acute mania of the ordinary kind; 2. Simple melancholia; 3. Epilepsy. At times atrophy of the optic nerve was a valuable aid to diagnosis, but this sign, if present, usually came on late in the disease. A case was narrated, however, in which this symptom distinctly aided the diagnosis, being present along with acute mania of the ordinary type, and at an early period of the disease. The cases chiefly dealt with in the paper were those which closely simulated epilepsy, the first manifestation of the disease being an epileptic fit, and the fits exactly resembling the *grand mal.* These cases were very liable to be mistaken for epileptic dementia, and the diagnosis was often very difficult at first. The most important diagnostic sign was the condition of the pupils. Very often these partook of the Argyll Robertson type, *i.e.*, they were inactive as tested by the natural stimulus, light, whilst they retain the normal movement and accommodation. Irregularity and inequality of the pupil were signs which had long been associated with general paralysis, but the Argyll Robertson pupil had only been recognised of late years, and was the least known although the most valuable sign. Cases of the epileptic type were related, in which the condition of the pupil alone enabled a diagnosis to be made, which was subsequently verified by the progress of the disorder. In fact it was not too much to say that, excluding cases of locomotor ataxia with mental symptoms, the presence of the Argyll Robertson pupil in any case of mental disorder was almost, if not quite, sufficient to stamp the case as one of general paralysis.

Dr. Stanley Gill said, whilst he complimented Dr. Wiglesworth upon his extremely original paper, at the same time he must take exception to the state of the pupil being so sure a diagnostic sign of general paralysis as Dr. Wiglesworth wished us to believe. General paralysis was far too variable a disease, both in its symptoms and pathology, for us to single out any one symptom, and rest our diagnosis upon it. All the cases with the condition of pupil described by Dr. Wiglesworth were those of women, one of whom was stated to be of loose character, and as general paralysis was comparatively rare in them, it was just possible it might have been of syphilitic origin.

Messrs. Bickerton and Clegg also spoke.

◆

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Friday, January 7th, 1887.

The President, Dr. Alderson, in the Chair.

Dr. Seymour Taylor read a paper on

THE ETIOLOGY OF PHTHISIS, AND ITS TREATMENT FROM A HYGIENIC STANDPOINT.

Phthisis he considered a condition or symptom having several causations: inflammatory, fibrous, tubercular or otherwise. The tubercular form might be described as bacillus phthisis, or owing to Koch's connection with the tubercle bacillus, the disease might be called Koch's phthisis. In his experience the bacillus tuberculosis was always present in tubercular phthisis. Tuberculosis, like cancer, may vary in its virulence, in some it may be general in its distribution, it may be quite a local process, tubercule is not singular in its behaviour, it attacks some localities by preference. It selects certain families or constitutions, apparently by preference and not by accident, the author then discussed the arguments which had been advanced against the infective theory of tuberculosis, and said that other factors were necessary for a man to catch the disease than the mere contact of the bacillus, while whatever the gate of infection might be—mucous or otherwise—an abnormal condition of the points of contact was a certain factor in the production of the disease. The blood contained bacilli after inoculation, and as in enteric fever a relapse may be occasioned by re-inoculation from an infected patch of ulceration, so it may be the case that extension of tubercular ulcer on the tonsil, or buccal cavity, or from strumous glands containing bacilli, indeed it is possible by inhalation to account for the multiple tubercular lesions which are met with in the lungs. The author then sketched briefly the life history of a tubercular patch, and discussed the origin of giant cells. He concluded by epitomising the causes which in his opinion rendered phthisis so virulent amongst us, and said that our cold, damp climate by favouring the prevalence of catarrh of the respiratory apparatus was directly responsible for a condition which allowed the tubercular parasite to flourish.

Dr. Blenkinsop also read a short paper on "Phthisis,"

THE OPERATIVE TREATMENT OF INTERCURRENT DISEASE IN TUBERCULAR PATIENTS.

Mr. Bruce Clarke read a paper on this subject.

After briefly discussing the nature of tuberculosis and its dependency on a specific bacillus, the author proceeded to show that it was almost impossible to remove by a surgical operation, the whole of the bacilli that had found their way into the body. The local manifestation was all that could be got at. It was clear, therefore, that an operation could only aim at removing a growth which was causing so much constitutional disturbance as to prevent the recuperative powers of the patient and the physician's remedies from exercising a due influence on the course of the intercurrent disease. After relating several cases of his own and of other surgeons in which such operative treatment had been practised with a greater or less measure of success, and after showing that such cases healed with success and ease. The author concluded by asserting that surgical interference was only justifiable when all attempts at cure without the knife had been tried and found wanting.

Dr. Thorowgood in the course of some remarks said that a depressed state of the nervous system was an important factor in the causation of phthisis.

The President said that a dry soil was an important preventive of phthisis. In the second decade men were much more prone to the disease than women.

Mr. Keetley and Brigade-Surgeon Curran made some remarks, and Dr. Thudichum observed that there was no climate in the world which was free from phthisis. He thought the Koumiss cure, advocated by the Russians, was of no real use. It was remarkable that since Koch's discovery of the bacillus, phthisis had increased all over the world.

Messrs. H. H. Taylor, Lloyd, Benham, and Dunn continued the discussion, and Drs. Seymour, Blenkinsop and Mr. Bruce Clarke respectively replied.

Dr. P. S. Abraham showed a selection of sections of tubercular organs in man and the lower animals, and specimens of the tubercle bacillus.

Messrs. Wright and Co., of New Bond Street, exhibited a large collection of instruments—sprays and inhalers.

◆

The Mortality of Foreign Cities.—The annual death-rates per 1,000 in the principal foreign cities, according to the last weekly returns communicated to the Registrar-General, are as follow:—Calcutta 41, Bombay 21, Madras 34, Paris 25, Brussels 21, Amsterdam 24, Rotterdam 29, The Hague 22, Copenhagen 22, Stockholm 20, Christiania 23, St. Petersburg 29, Berlin 20, Hamburg 33, Dresden 22, Breslau 33, Munich 26, Vienna 25, Prague 29, Buda-Pesth 32, Trieste 32, Rome 28, Turin 22, Venice 20, Cairo 48, Alexandria 37, New York 29, Brooklyn 24, Philadelphia 19, and Baltimore 14.

Vital Statistics.—The deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 24·1 per 1,000 of their population, and were—Birkenhead 23, Birmingham 22, Blackburn 30, Bolton 21, Bradford 19, Brighton 20, Bristol 26, Cardiff 30, Derby 20, Dublin 36, Edinburgh 20, Glasgow 31, Halifax 24, Huddersfield 23, Hull 22, Leeds 28, Leicester 24, Liverpool 28, London 23, Manchester 31, Newcastle-on-Tyne 27, Norwich 28, Nottingham 20, Oldham 19, Plymouth 29, Portsmouth 17, Preston 29, Salford 21, Sheffield 22, Sunderland 19, Wolverhampton 31. The highest annual death-rates in these towns last week were—From measles, 1·9 in Wolverhampton and in Liverpool, 2·0 in Newcastle-upon-Tyne and in Halifax, 2·6 in Leicester, and 3·0 in Leeds; from scarlet fever, 1·1 in Norwich, 1·2 in Bristol and in Manchester, 1·8 in Blackburn and in Sheffield, and 2·0 in Sunderland; from whooping-cough, 1·4 in Bristol and in Plymouth, 1·5 in Preston, 1·6 in Sunderland, and 2·9 in Huddersfield; and from "fever," 1·1 in Birkenhead, and 1·4 in Plymouth. The 36 deaths from diphtheria included 18 in London, 5 in Birmingham, and 4 in Glasgow. Small-pox caused no death in any part of the United Kingdom.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 26, 1887.

SIR JAMES PAGET ON THE FUTURE OF PATHOLOGY.

THE teaching of the eloquent though brief address delivered last week by Sir James Paget in his office as President of the Pathological Society of London is well and simply summed up in an expression employed by the orator himself, to the effect "that with true work true good will come." The acceptance of a belief in this aphorism is the beginning of pathological wisdom, in the same way and as much as it has been the commencement of every great achievement in medicine; and no one is more fitted than the veteran surgeon who gave utterance to the truism to impress on the minds of his junior fellow-labourers in the field of discovery, how essential it is to gird themselves with such assurance as he confidently offers for their acceptance. Sir James speaks to us with an authority that none can impugn; his language is the language of experience, which none who listened to him can claim to have exceeded; and though there runs throughout the periods of his address the plaintive echo of a natural longing for repose, there is still apparent in it the inextinguishable desire to know more and deeper which is the inseparable attribute of genius. Again, repeating his own eloquent words, "For every increase of knowledge brings before us a larger and clearer view of the immeasurable quantity which is still to be gained. The more we know, the more can we see, if we will, how much more there is that we do not know." And we might add that it is the restless spirit of inquiry that is animated by such knowledge that is answerable for every advance that is made, a spirit that exists as a consequence largely of the influence and example of lives such as that of the honoured and beloved President of the Pathological Society himself.

Sir James seeks not to propitiate dreamers in his descriptions of the work that lies before the pathological student. The burden of his cry is work, unceasing practical labour, investigation of active living tissue in every one of its relations, physical, chemical, and physiological as well as clinical, and of the minutest possible description. He defends the practice of medicine from the charge of empiricism on the ground that even among empirical facts, so-called, "modern scientific work may win great riches for pathology;" and he points out how specific medicines which above all others have obtained their position as a result of the experimental (empirical) employment are very frequently invaluable from a diagnostic point of view also. And thus he goes on to affirm "they prove differences among diseased conditions that in other things appear alike. The epilepsy which is averted by the habitual use of bromide of potassium cannot depend on the very same conditions as that which is not so averted; the ulcer which heals under the influence of mercury cannot be of the same kind as that which looks like it but does not so heal. Thus, as we all know, these medicines are tests; and we may guess that each of them detects the presence of some material belonging to the disease which it cures. Here, then, is work for the scientific practitioner; he may find the material and more, if he will observe the facts in practice much more minutely, and record and collect them, and bring to bear upon them as much light as possible from other sections of pathological science. They will yield more knowledge, and his practice will be promoted to a better title than empirical."

In this quotation the path to be steadily pursued in the future is clearly set forth, and encouragement is offered to every one engaged in active professional duties to lend his aid in raising up the growing fabric of pathological science. It is the teaching of a master who would have the number of his disciples limited only by the number of those qualified by mental endowment and the training of his powers of observation, "to watch, perceive, and record," and he truly says that this great task "in the variety and complexity of its problems offers work sufficient for the employment of nearly every variety and opportunity of the scientific mind. . . . not only for the anatomist and physiologist, but for the clinical observer, the experimentalist, the minutest microscopist, the statistician, the chemist, the naturalist, the historian, the psychologist, and yet more." No man, however, can be all these, and hence each will do his share best who follows in the direction to which his special genius prompts him.

This is a broad, a just, and a fortunate view of the subject to be set forth by such a teacher; and as those who listened to the address enthusiastically proved their appreciation of its importance, so will the whole profession likewise be grateful for so clear an exposition of the needs of the future of pathology.

◆

HOSPITAL FUNDS.

It is interesting and instructive to notice an appeal for funds which appeared in a recent number of our contemporary *Truth*, from Lady Margaret Sandhurst, coinciding in point of date with that which has been put forward on behalf of Guy's Hospital. Lady Sandhurst applies in the interest of a work which she describes as one of peculiar character, and the information which follows fully bears out her description. Some three years ago, according to her Ladyship's account, a work was commenced for the purpose of showing what could be done for the cure of "deformities, disease, and nervous affections," by magnetic (mesmeric) treatment, and the results of the "work" are stated to have been remarkably successful, indeed, in some instances, "little short of miraculous," seeing that cures were promptly effected in cases "pronounced by the faculty incurable and hopeless." It is discreditable that even an institution where such unexampled successes are recorded should suffer from the very general complaint of a lack of funds which can only be due to a want of appreciation on the part of an usually impressionable public. That "funds are urgently needed" we can readily believe, magnetic massage is not being a treatment which appeals *à priori*. to the minds of most intelligent people.

This touching appeal is only one of a whole category, the drain of which upon the purse of the benevolent public must be held responsible for the impecuniosity of many, nay most, of the great and deserving institutions of the metropolis. The foundation during the last century of a host of "special" hospitals, to a great extent private speculations, has, in combination with other factors, utterly disorganised the financial arrangements of hospitals dependent for their support on voluntary contributions. To such a pass has this disorganisation come, that unless some remedy be brought to bear upon it, and that speedily, we shall find ourselves face to face with the problem of hospital maintenance, of which only two solutions have been suggested. One is to cut down the expenditure to the limits of income—a procedure which would entail the closure of whole wards—and in some cases of whole hospitals, and the other would be the creation of a hospital board which should take over the administration of funds for the relief of the sick and suffering, and make up any deficit by means of a general rate. No one will probably contemplate such a change with equanimity. It may be argued that such an arrangement would be conducive at once to efficiency and economy. The efficiency of our present hospital arrangements doubtless leaves little to be desired, but from an economical point of view, reforms are both possible and desirable.

The control at present exercised over the disposal of funds subscribed for the purpose of hospital expenses, is not such as one might wish for, even in the larger and better organised institutions, and as regards the management of the smaller institutions it may be said to be simply non-existent. Take the majority of these homes and special hospitals for magnetic or other treatment, what guarantee have the public as to the proper distribution of the funds subscribed. They may be, and we will venture to believe that they *are*, properly managed, with every regard to economy and efficiency, but money matters in which the public is asked to participate, must be conducted on strictly business principles. Even if we were assured of the proper financial administration of these second and third-rate institutions, they would still be open to the objection that they necessitate an unduly large appropriation of funds for the expenses of management, quite out of proportion to the relief which it is in their power to afford. Moreover, the danger is always present, as a consequence of their mediocre importance, that the government may fall into the hands of an irresponsible clique, who manage the affairs of the "home" or hospital more with a view to their own interests than for the benefit of the public. Many of them are well known to be neither more nor less than *succursales* of this or that specialist, who uses them as a nursery garden for his private practice. The secretary in such cases, in addition to his duties as secretary of the institution, discharges that of amanuensis to the physician or surgeon whose influence is paramount. Such a state of things is a crying scandal, and renders some efficient control indispensable. It is a gross abuse that such *quasi* proprietary institutions should be allowed to claim and receive from public funds, sums of money to be disposed of by an irresponsible body of men, of whose integrity and business aptitudes no guarantee whatever is offered.

The situation is now not far from a solution, and in the interests of the present system of voluntary contributions, which has much to recommend it, it behoves subscribers to insist on a more rigid inquiry into the employment and distribution of the funds which they furnish, and the amount of which is constantly below the expenditure. In default of some carefully planned and carried out form of this kind, Government will doubtless, at no distant date, be requisitioned to deal with the matter.

◆

THE PROFESSORIAL SQUABBLE AT EDINBURGH.

The correspondence which has been sent to us for publication reveals such a serious state of tension between the learned Professor of the Institutes of Medicines in the University and his assistants that on public grounds and in the interests of the profession we feel ourselves compelled, to draw attention thereto. It throws light, moreover on what our Edinburgh correspondent referred to (Jan. 12) as the "unexpected resignation" of Mr. Herbert H. Ashdown, M.B., Senior Demonstrator of Physiology to the University of Edinburgh. For some weeks rumours of a most unpleasant character have been current in scientific—and, we fear, in non-professional—circles all over the country as to the immediate cause of that hurried step. The letters which follow afford suggestive explanation. But it appears to us surprising that matters of so grave import as those indicated by the second paragraph of the apology and retractation should have been allowed to lead to the resignation of a successful teacher and able investigator without the institution of a full and searching inquiry into the nature and truth of the charges. The fact that an apology of this humbling character has now been proffered suggests that the status of demonstrator or assistant in the Scotch Universities can hardly be so defined and independent as it ought to be. An assistant ought to have some other resource in such difficult circumstances than an enforced resignation. We take for granted that it was a serious loss in many ways to Mr. Ashdown to give up his post and yet, under existing arrangements, he was compelled to resign, that he might escape from the perilous position in which his superior had placed him. University assistants ought undoubtedly to be University servants, just as the professors are. They must be responsible to the same authority, and, in common fairness, they should have the same court of appeal. From every point of view it is most unsatisfactory that they be the paid dependents of individual professors. Had Mr. Ashdown's position been established apart from the Professor with whom he was associated, this unpleasant *rencontre* could not have occurred.

Granted that the conduct of any University official is objectionable, there should be a tribunal to which the aggrieved "citizens" may apply directly, with some reasonable prospect of redress, and to the jurisdiction of this tribunal all University servants must be equally amenable. But we forbear from further comment. The letters sufficiently explain themselves. It should be added, however, that we are credibly informed that this is the third or fourth resignation that has unexpectedly occurred in connection with the same department. This cannot represent a satisfactory state of affairs.

3 North Charlotte Street, Edinburgh,
January 18, 1887.

Sir,—I beg to enclose a copy of a holograph letter addressed to me by Professor Rutherford, M.D., F.R.S., containing his apology for, and his complete retractation of, the language used by him to me personally, and about me to others, on the occasions referred to in that letter.

The language which Professor Rutherford used to me on the 11th December last was of such a nature as to leave me no alternative but at once to resign my appointment as his Senior Assistant, which I did.

The fact of my resignation and the circumstances which led to it, and the remarks made by Professor Rutherford upon it to his class and to others have given rise to comments in various quarters. I therefore feel it to be necessary to give to Professor Rutherford's apology and retractation the same publicity, so far as I can, which has been given to the incident which led to my resignation, and I therefore send you the enclosed copy letter for the purpose of showing the entire absence of any foundation for the language which Professor Rutherford saw fit to use to and of me.

I am, Sir, your obedient servant,
Herbert H. Ashdown, M.B.,
Late Senior Demonstrator of Physiology
in the University of Edinburgh.

---

14 Douglas Crescent, Edinburgh,
January, 17, 1887.

Dear Sir,—I beg to apologise for the remarks made by me relative to you at our interview on Saturday the 11th December last, and to express my deep regret for having on that occasion used expressions to you which were understood by you to imply charges seriously affecting your moral character. On consideration I admit that the expressions which I unfortunately used were such as naturally to produce this understanding; but in justice to myself, as well as to you, I desire to say that it was not my intention to make such charges, for which there is no foundation.

I further apologise and express my deep regret for having charged you both personally and to others with objectionable manners on some occasions. I admit that you gave no occasion for any such charges, and I unreservedly withdraw them.

I also beg to express my sincere regret that what I said caused your resignation as my Senior Assistant.

Yours very truly,
(Signed) W. Rutherford.

To Dr. Herbert H. Ashdown.

◆

Notes on Current Topics.

Brain Surgery.

Facts do not appear to favour the prosecution of this branch of the surgical art, and the more they are looked into by the light of results the less do they support the views of the F.R.S., who painted them in such glowing terms recently in a contemporary. Unfortunately for that (his, F.R.S.'s) view, says Dr. Goodhart, in the Pathological Society's Transactions, "I had in my mind another case in which, according to the diagnostic skill of Dr. Ferrier himself, a cerebral tumour was judged to be a fit case for the attempt at its removal. The man died before the attempt was consummated, and the tumour was found to occupy the entire thickness of the anterior third of the affected hemisphere. *This is the way in which* (italics ours) *most of these cases reject the advances of surgery.* Extensive disease in the white matter gives so little evidence of its presence. For the last thirteen years I have been making post-mortem examinations at Guy's Hospital, and during that time, although I have come across many cases of cerebral tumour, I do not remember to have seen a single case in which the tumour was at the same time *accessible* and so *localised* as to be capable of successful surgical attack. . . . When, therefore, I read that the case to which I have alluded has opened the door to successful treatment of scores of similar cases I can only say that a consideration of all the facts and particulars of that class makes one very doubtful as to the accuracy of F.R.S.'s judgment. I am the more inclined to take the opposite view, viz., that it is very doubtful whether in the region of cerebral tumours other than inflammatory, *surgery has any future worth mention before it.*" So speaks an able pathologist as well as a practising physician of specialised experience on the point, and we trust that the authorities of our hospitals, surgical and otherwise, will take stock of these statements, and either prohibit entirely or reduce to a minimum, these ingenious, but, withal, useless operations. Assuredly, if they do not, some irate friend or relation will interpose and call them or their operator to a severe account. Woe be to him who ignores such teaching and such facts as we have just reproduced. However disinterested he may appear to be, no jury could "find" for him in face of such damning evidence as this of Dr. Goodhart's undoubtedly is. It more than upholds

Surgeon-General Gordon's inquiry as to the *cui bono* of such wild surgery or mere worthless experimentation. Confirmatory also of this view, we have before us opinions of the Committee on "Morbid Growths or Intra-cranial Tumours," as follows:—"The Committee felt that it would be impossible to pass over the question of surgical treatment in intra-cranial growths. Yet out of the fifty-four tabulated cases *two only seemed suitable for removal*. Again, "the fact that intra cranial growths may exist in certain parts without giving rise to symptoms referable to such parts, their tendency to compress and displace without destroying, and lastly, the pressure they often exert on remote parts *very often render their localisation a matter of pure conjecture.*" Verily Dr. Gordon may again repeat his *cui bono* without any expectation of getting it satisfactorily answered, and if these several statements are—as they undoubedly are—true, then might Ferrier as well have been beating the air as boring holes into the crania of monkeys, or cutting slices out of their contents.

Testimonials to Proprietary Medicines.

An American contemporary has found it necessary to enter a protest against the giving of certificates by medical men in favour of proprietary medicines. It is to be regretted that such a protest should be called for, but the practice is certainly one which calls for the strongest disapprobation. It is not altogether unknown in our own country, as a glance at the advertisements and circulars of proprietary medicines will show, but it is very rare indeed that a man of any standing or reputation has allowed himself to be coaxed or deluded into such a breach of etiquette and good taste, not to say honesty. Too much caution cannot be shown in expressing satisfaction—in writing at any rate—even of drugs or preparations which at first sight may appear to be outside the category of "patent medicines." If a drug or preparation be really possessed of the qualities claimed there are proper means of bringing it to the notice of the profession, and none other should be countenanced.

Thirst in Infants.

Thirst is a sensation which is relieved by the introduction of some liquid into the alimentary canal, consequently, a very general impression prevails that milk, being a liquid aliment, is at the same time a drink which will appease thirst. This belief, however, is erroneous. Milk, the type of a food, calms hunger but often only aggravates thirst, especially when digestion has begun. It is for this reason that, much to the astonishment of mothers, infants often cry for more soon after a copious meal of milk. To put the child again to the breast is only to add fuel to fire and to pave the way for a serious attack of indigestion. The explanation is not difficult. The first thing that happens when milk is introduced into the stomach is the precipitation of the casein in the form of curds, the digestion of which is apt to overtax the supply of gastric mucus, more especially as the supply is by no means abundant in infants. The curds thus incompletely macerated tend to form lumps, sometimes of great size, which disorganise and fatigue the functions of the stomach. All circumstances which tend to lessen the proportion of liquids to solids in the stomach, give rise to the sensation of thirst, and if the mother will only supply, at the proper moment, a genuine liquid, such as water, digestion recommences energetically, and goes its course. No risk can attend giving infants now and again a teaspoonful or two of water, and the best way is to give it tepid and slightly sweetened.

Suicide by Dynamite.

Some people are dissatisfied with the methods of suicide consecrated by immemorial usage, and prefer to make use of agents which modern science has placed at their disposal. Dr. Zalaski has recently published two somewhat curious cases of this description. In one, a man, on being arrested for poaching on fish preserves by means of dynamite cartridges, attempted to commit suicide with one of them. He placed it under his chin, but the effect of dynamite explosions being more marked downwards than upwards, the only result was to blow off his right hand, damage the left hand, and mutilate his face. Number two was more successful. He lay down on the ground, placing the cartridge on his chest. After five unsuccessful attempts to light a match, the sixth took fire and exploded the cartridge. The thorax and abdomen were completely emptied of their contents, and the corresponding parts of the vertebral column and ribs were also missing. The other parts of the body were not injured.

Cruelty to Animals.

During the recent snowstorms which for many days blocked our streets the climax of suffering must have been reached by the helpless animals goaded on by the lash of the whip to bear civilization's burdens. Not a word of remonstrance was uttered by the screeching sisterhood of the Antivivisection Society, nor that of the Cruelty to Animals Society, both of which receive large sums of money for the ostensible purpose of performing some such duty to the animal creation. The supporters of these societies are apparently not to be aroused by the sufferings endured day by day by the cab, cart, and carriers' horses, over-driven and cruelly ill-treated in the streets of London; nor by the more harrowing tale of the cruelties practised in the cattle markets of the world, which surely might be expected to stir up humanitarians in every country to action. A truly horrible tale of suffering comes to us from Texas. The "State official," Colonel Cunningham, reports to "The Bureau of Animal Industry" that in nine of the cattle-breeding states the losses arising during the past year from drought, starvation, and exposure to the weather amounted to the enormous number of four millions of animals out of sixteen millions. This large number does not include losses from disease, nor the loss of many young animals not strong enough nor old enough to follow the herd in its daily struggle for existence. One in every four of the animals bred dies a miserable death, either from drought, want of pasture in summer, and to which in winter is added frost and snow. Cattle breeders, it appears, are totally indifferent to the sufferings due to crowding the plains and pasturage with beasts, an enormous percentage of which they know will be lost to them, but still leave enough whereby they may grow rich. In such a case the storms of winter and the snow drifts known to destroy tens of thousands heads of cattle at a time offer a far more merciful death than that received at the hands of their merciless drivers. If, however, neither the vivisectionists nor the Cruelty to Animals Society subscribers look upon the cruelties practised upon these thousands of tame animals as no business of theirs, then may we direct their attention to what is going on nearer home. Our Parisian neighbours, a week ago, to show their sympathy with the sufferings of the Southern peasants from recent inundations, hit upon the revival of the bull-fight as the best means of raising a fund. The bulls brought into the ring were most mercilessly goaded and tormented by their persecutors, and to the great gratification of thousands of brutal sightseers, who freely paid their money to witness this inhuman sport.

Verification of Hospital Attendances.

We understand that the Branch Medical Council for Ireland has, on the motion of Professor Haughton, adopted a resolution in favour of the verification of hospital attendances by inspection by a special officer. Such a decision would be very creditable to the Branch Council, most necessary to secure the *bona fides* of Irish medical education, and most advantageous to the student who is honestly pursuing his studies. Verification of signatures need not be feared by any student who is honestly working at his business, nor by any hospital which is honourably carrying out the arrangements for checking attendances, and any pupils or teachers who object to the proposed inspection invite suspicion as to their *bona fides*.

Catching Cold at School.

A very appreciable amount of damage is done to health by the lack of experience of boys at school in the matter of hygiene. After several hours spent in the over-heated, but not over-pure atmosphere of the class-room, the lads are sent without transition into the playground, which at certain seasons of the year is glacial in temperature. Some of them play marbles or some other game not involving muscular effort, until too numbed to continue, while others indulge in violent exercise, until, out of breath and uncomfortably hot, they placidly seat themselves until sufficiently cool. The precautions which would suggest themselves to the adult provided with an average amount of foresight naturally do not occur to boys, or if they occur, are disregarded. The result is that a comparatively large proportion of the boys suffer more or less severely from maladies *a frigore* Acute pneumonia and bronchitis, pleurisy and acute rheumatism, to say nothing of influenza and quinsy, are the reward of their ignorance or of their temerity. It behoves those who are in charge of these youngsters to make up for the incautiousness of youth by enforcing the observance of a few elementary but useful precautions. On leaving the school, none should be permitted to loaf about or to take part in games which do not involve active bodily movement. Overcoats cannot and should not be insisted upon, for the simple reason that if they were, the earliest possible opportunity would be seized of taking them off and thus doubling the chances of catching cold. Probably the simplest and least irksome plan would be to provide each boy with a jacket of the kind generally known as the "Cardigan" jacket, a close woollen garment which prevents sudden chills, and does not interfere with the liberty of motion which is such a strong passion with healthy boys. Its use ought with equal reason to be enforced in the football field, where the slightest negligence may be serious, from the arduous labour involved in the game and the flimsy garments which are worn thereat. The indications are difficult to fulfil, and they might be the means of protecting our boys against the consequences of their ignorance or inexperience. We commend them to the notice of the proper authorities.

M.D.'s for General Practitioners.

It is reported on good authority that the Irish Colleges have taken fire upon the proposal that the London Colleges should seek powers to make all their conjoint diplomates into M.D.'s. The Irish Colleges do not at present put forward any claim to such privilege, and, as far as we know, they have no desire to put themselves in controversy with the University of Dublin or the "Royal" by doing so, but they will be very likely to insist upon being granted their share in any privileges which may be conceded to the London Colleges, and *sequitur*, will resist all exceptional and one-sided legislation for the purpose.

The Royal Army Warrant.

We have caused the Warrant which has been recently issued to be examined for the purpose of ascertaining whether its provisions materially affect the interests of the Medical Department, but we cannot find that they do. The "service" newspapers have represented that the Warrant abolishes all relative rank of the medical staff, but this is not the fact, for the clauses dealing with that matter have reference only to departmental officers who hold honorary rank.

The Metropolitan Water Supply.

Professor Dr. Frankland, in his last month's published report on the water supplied by the London Water Companies, says:—"The water of all the Companies was exceptionably polluted ; none could be described as a perfectly safe potable water." We are by no means surprised to find the Thames water in particular very bad, as for days and weeks together large areas of the upper Thames, and above the intake of the water companies, were flooded, and bringing down into the basin of the river off the land tons of manure and decayed vegetable matters. The late Colonel Bolton in the last report made to the Government, said, "The Thames water is in such urgent need of purification at the sources of supply that we are in danger from contamination, and that to secure the water drinkers of London from some epidemic visitation, large works must be undertaken without delay." If this be so, and there can be no doubt on the matter, the Common Council of the City of London must be congratulated on the determination it has come to to sink a well—in the first place to test the comparative cost of a supply of good and pure water, as against that of the water-rate charged by the Companies; and next, whether. the quantity of water obtainable can be depended on If it is found to be quite within the bounds of possibility for a district authority or any individual to sink a well, the grievances of the London water consumer will disappear. We have all along been of opinion that the London chalk beds will afford an unlimited supply of pure water, and the City of London is adopting the surest course of bringing the Water Companies to reason by the good old fashion of competition.

A Novel Cause for Action.

One of the most curious actions for damages of which we have heard for some time was that brought by a Mr. Brett against the proprietors of the Holborn Restaurant for damage sustained by swallowing a needle and thread in some spinach which was served at a Freemasons' banquet in April last. He mentioned the fact of his having swallowed something which scratched him to one of the waiters, but did not complain to the defendants until June, when the effects of the meal had become apparent in some troublesome fistulæ in the neighbourhood of the rectum. It will be interesting to know what liability has been incurred by the negligence involved in serving up spinach *cum* needle. The difficulty of course lies in the necessity of proving that the needle in question was swallowed at that particular meal.

Begging Propensities.

Some time ago we had occasion to express disapprobation of the system under which authors were coolly requested to favour this or that medical library with a copy of their works. We regret to see that the plan is still adopted by certain bodies, notably by the Birmingham Medical Institute. Surely the medical men of Birmingham are rich enough collectively to pay for such books as they require. It is no doubt an excellent idea to bring together the materials of a good library of reference, but there is no possible reason why this should be done at the expense of the author, whose pecuniary reward is small and uncertain under the best of circumstances. Such unblushing mendicity is unworthy of the institute which indulges in it, and we hope will soon be relinquished in favour of a more just and equitable plan.

Nephrectomy for Scrofulous Disease.

A very successful case of removal of the kidney for scrofulous disease was brought before the Glasgow Medico-Chirurgical Society on Friday last by Mr. Henry E. Clark, one of the surgeons of the Royal Infirmary. The patient, a married woman of 26, has gradually developed the signs of abscess in the left loin, and as the urine contained pus and epithelial *débris,* this was diagnosed as being a renal abscess. The kidney was incised in Jan. 1886, and about a pint of pus evacuated, but the sinus continuing to discharge and other abscesses forming in the kidney, extirpation of the organ was decided upon. This was done in August last, by the lumbar incision without any difficulty, the only incident worthy of note being the slipping of the ligature at the time of separation of the kidney from its pedicle. The patient made rapid recovery, and is now in perfect health with a normal excretion of urine. Mr. Clark specially dwelt on the importance of the evidence obtained by the use of the ureteral catheter, as showing the other kidney to be sound, and showed that in the female the introduction of a catheter into the ureter was safe, easy, and satisfactory. He referred to the statistics of extirpation for scrofulous disease, and objected to the conclusion of Gross that the ventral was safer than the lumbar incision in such cases. He also made some observations on the best position for the lumbar incision in relation to the last rib and pleural cavity. We congratulate Mr. Clark on the success of this very important operation. Successful nephrectomy marks a new era and a new triumph in surgery. M Paul Segond gives the particulars of two successful nephrectomies, the one for suppurating hydro-nephrosis, and the other for painful floating kidney, in *The Annales des Maladies des Organes Génito-Urinaires,* for this month.

Association of General Practitioners.

A meeting of the Council of this Association was held at Exeter Hall on Wednesday, January 19th. Several important resolutions were passed, approving of the scheme for placing an M.D. degree within the reach of London students, and also asking for a Royal Commission of inquiry into the present constitution of the Royal Colleges. The chair was taken by the President, Mr. Wheelhouse, of Leeds, who insisted on the fact that he was a *bona fide* general practitioner, and was therefore able to speak with propriety on their behalf.

Ungar, Bonn (*Cbt. f. Klin. Med.,* 45-86) has repeated antipyrin with success for hæmicrania, which he applied when other means failed. Dose 1·0 grm. or in exceptional cases 1·5 grm. in a capsule or wafer, to be repeated every hour until an effect is produced.

Sir William R. E. Smart, M.D., Inspector-General of Hospitals, has, we understand, been awarded a good service pension of £150 a year.

Dr. John Woodman, Medical Officer of Health of Exeter, reports that, owing to the severe epidemic or measles in the early part of last year, the death-rate of that city, which is usually a low one, was 96 in excess of the previous year, and 1·3 per 1,000 in excess of that of the other large towns from the same cause.

France.

[From our own Correspondent.]

Discussion on Hydrophobia.—At the last meeting of the Académie de Médicine, M. Peter spoke on a case of hydrophobia which terminated fatally, although the patient passed through the hands of Pasteur. The patient, a young man, forty-eight hours after being bitten, went to M. Pasteur and three injections were made each day during twelve days. Six weeks subsequently he succumbed, no convulsion was observed, but weakness and paralysis. M. Peter, in terminating, said that the pain was not attributed to the bite, but to the points of injection, and that the chief phenomena were paralytic and not convulsive. M. Dujardin thought that the convulsions of M. Peter were not so defined as might have been believed. The death was not one in which the symptoms of hydrophobia predominated. He recalled the case of a child who was bitten by a mad dog and who a month subsequently having received a blow in the side experienced great pain at the spot, went to bed and died with convulsive phenomena. The autopsy was made and the bulb injected into other animals did not produce the symptoms of hydrophobia. The child succumbed to uræmic troubles. Other members were of the opinion of M. Dujardin.

GUNSHOT WOUNDS OF THE ABDOMEN.—At the Société de Chirurgie M. Trelat spoke on gunshot wound of the abdomen. A child who had received a wound from a revolver in the abdomen succumbed, and the autopsy showed that the death was due neither to peritonitis nor to perforation, but to intestinal occlusion produced by narrowing of the intestine consequent on partial resection of the canal. M. le Dentu said that he had seen several cases of abdominal wounds with perforation of the intestine which succumbed to peritonitis in from four to five days. M. Tillaux said that wounds of the small intestine were not necessarily fatal, and that spontaneous cure is not impossible. He considered that laparotomy was very hazardous and should be reserved for extreme cases.

THE TREATMENT OF GOITRE is very varied, and the results have been frequently disappointing. Women are attacked so much oftener than men that the deformity is much more felt. A Dr. Dugent has treated for many years, with almost invariable success, the unsightly tumour by injections of tincture of iodine of the ordinary strength. The syringe of Pravaz was the instrument used, and the first injection was made in the part the most resisting and fleshy. Frequently one injection sufficed, but more frequently it was necessary to repeat it several times at an interval of eight days. The quantity used each time was from a half to a full syringe. The injection was followed in most cases by very slight reaction, and which did not last more than two days.

THE CENSUS OF FRANCE.—The French press is sounding the alarm about the results of the recent census. The *Journal Officiel* has just published the *compte rendu* of the work of May last. The population of France at that date was 38,218,000, showing an increase of only 546,000 over the figures of 1881. Thus France has 10,000,000 less than Germany. Further, 1,000,000 of the total are foreigners who could not be counted upon in case of aggression. There is another verity which is yet less consoling and that is the slight increase, is still diminishing, when compared with former years. From 1876 to 1881 the increase was put down as 776,000. The reason for this decrease is not to be found in the physical temperament of the race, but their unwillingness to procreate. Malthusian principles are generally adopted in the towns. One child, or at the most two, are accepted, but there a strong line is drawn. Means are adopted to prevent conception, of which the least culpable consists in the husband, *battant en retraite*. If conception does take place there are women ready to cut it short for a trifle, and if the full term were arrived at by some mischance, why, it is easy to do away with the child by quenching its existence, and the jury is so indulgent towards young girls who thus dispose of the fruit of their *faiblesse* by committing a crime! In this very day's paper I read the case of a girl, nineteen years, who was tried for smothering her offspring as soon as it was born. She confessed frankly the infanticide and gave all the details. The jury acquitted her! The law relating to parental responsibility in such cases is very loose and that is why so many children are sacrificed. French papers which are as ignorant as they are inventive in what they furnish to their readers, are for ever holding up *la perfide Albion* as one of the most immoral countries, forgetting that in France immorality does not use nor require the veil which is wrapped even but thinly around vice on the other side of the Channel.

◆

Scotland.

[FROM OUR OWN CORRESPONDENTS.]

UNIVERSITY OF EDINBURGH.—MEMORIAL SERVICE FOR THE LORD RECTOR.—On Tuesday, 18th January, the University assembled in St. Giles' Cathedral to give expression to their deep sense of the loss which its members had sustained in the sad death of their Rector, the late Lord Iddesleigh. The service was held at the same hour as the funeral obsequies in the south. There was a large assemblage of the University authorities and of the general body of its students. A special choral service had been arranged, and a short sermon was preached by Dr. Cameron Lees. The students of the University have keenly felt the removal of the late Earl, and they have testified, in many ways, their deep sympathy with the mourning family.

ST. ANDREWS UNIVERSITY.—A memorial, signed by 789 graduates of St. Andrews University, has just been presented to the Scotch Secretary, praying that an endowment be found for two additional professorships, viz., of Anatomy and of Botany, so that St. Andrews may be enabled to give two *anni medici* to medical students, after completing which they might proceed to any of the hospitals of the United Kingdom, returning to the University for graduation. In connection with the memorial a deputation has awaited on Mr. Balfour and the Lord Advocate to urge the measure.

ROYAL INFIRMARY OF EDINBURGH.—The adjourned annual meeting of the Edinburgh Royal Infirmary was held on Monday, the 17th. The annual report was submitted and showed that during the last year 8,088 in-patients and 25,500 out-patients had received treatment and advice free of charge. The skin and throat departments continued successful. The observation ward for doubtful cases—removed from the general buildings—had now been completed. Their ordinary expenditure was less, though the number of patients treated was greater, than in previous years. The warm thanks of the managers are recorded in favour of the members of the staff who so efficiently have discharged their respective duties, especially to Dr. Joseph Bell, who, last year, retired by rotation.

EDINBURGH HEALTH SOCIETY.—The last lecture in the seventh course of the Edinburgh Health Lectures was delivered on Saturday, the 15th, by Professor Stirling, Manchester. The subject was "Tear and Wear." Professor Stirling illustrated in many ways the applicability of the principle of the transformation of energy to the vital processes which occurred in the human organism. Professor Chiene, who occupied the chair, moved a hearty vote of thanks to the lecturer. Thereafter, Mr. Cox, of Gorgie, submitted the annual report of the Health Society. They had now finished seven courses of most excellent lectures. This year the special lectures to men and women had not been delivered, as it was difficult to obtain lecturers, but the committee hoped to include them next year. The membership had rather diminished, but they were of opinion that this was only temporary. They had most warmly to thank the lecturers, who had freely given their valuable services to the committee. Already 550,000 copies of lectures had been sold. The report was adopted, and the Committee of Management re-elected.

Sick-Room Cookery.—A course of demonstrations on Sick-Room Cookery has just been begun in connection with the Edinburgh Royal Infirmary. This has now come to be regarded as one of the regular parts of the medical curriculum in Edinburgh, and Mrs. Hall is to be congratulated on the efficient way in which the arrangements are carried out.

Glasgow Medico-Chirurgical Society.—At a meeting of the Glasgow Medico-Chirurgical Society, held in the Faculty Hall, on Friday, the 21st inst., Dr. J. Crawford Renton showed patients on whom surgical operations had been performed, and Mr. James Carter, F.R.C.S.E., read a paper "On the Comparative Anatomy of the Seminal Vesicles, Prostate] and Cowper's Glands and their Supposed Functions." Mr. Henry Clark showed a successful case of removal of the kidney for scrofulous disease, which is referred to in another column.

Health of Greenock.—On the 18th inst., at a meeting of the Police Board, Dr. Wallace, Medical Officer of Health, stated that during the four weeks ending 1st January there was a total mortality of 122, which is equal to an annual rate of 21·1 per 1,000 of the population. Taking into account the severity of the weather, the prevailing depression in trade, and the consequent poverty of large numbers of the population, these figures could not but be regarded as satisfactory. For the whole year the results were even more favourable, the deaths being 1,290, which gave a rate of 17·25 per 1,000 of the population, and one quite unprecedented in the sanitary history of the town. To show how much the public health had improved he stated that in 1875 the rate was as high as 34.29, or about exactly double that of 1886.

Case of Alleged Ham Poisoning.—Early on the morning of Sunday, the 16th inst., four lads, aged respectively 17, 13, 7, and 4 years, were taken to the Northern Police Office, Glasgow, in an unconscious state and believed to be suffering from poison. They were at once conveyed to the Royal Infirmary, where the suspicions were confirmed by the surgeons in attendance, though it was stated that the lads were not dangerously ill. This led to inquiries being made, when it turned out that late on Saturday night the whole family had partaken of ham, onions, bread and tea for supper, and had retired to bed about 12 o'clock, all being apparently in good health. Three-quarters of an hour afterwards the youngest boy became ill and vomited, and shortly afterwards the others became ill, and were conveyed in an unconscious state to the Infirmary. Neither the father nor the mother were affected. The poisoning was believed to be due to unsound ham.

Correspondence.

THE LAPAROTOMY EPIDEMIC.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Dr. Keith has inverted the words and sense of my letter. What I said was that I was intimately acquainted with his opinions, and entirely agreed with them. I spent the whole afternoon of February 18 in his house, listening gladly to the free and unrestrained expression of his opinions on the debated subject. I would readily subscribe to all of them, and I shall now proceed to show my committee, by published cases, that our practice is not so dissimilar as h hastily imagines. Not even Dr. Keith is always successful, as we know to our sorrow in this district, nor his judgment infallible. By his own admission, he has operated upon a far greater number of cases than our senior metropolitan authority, and many of them since the recent visit of his distinguished son to Birmingham. Indeed, considering that Dr. Keith has command, I believe, of only seven beds, while we have thirty-three, and that his fame has been made in another direction, I am genuinely surprised to learn that he has found occasion and opportunity to have recourse so frequently to what he now denounces. I do not question that he has written down his conscientious convictions of the moment, but also I do not forget that more than once in his long and honourable career he has finally adopted what for a time he vigorously opposed. There is no one whose writings I have studied with so much devotion as those of Dr. Keith, and none whose work I more admire, and strive to imitate; but I must confess I never knew him to utter or to write a generous word of any living man in his own line of practice on this side of the Atlantic. And I believe the Edinburgh school to be more truly represented by his colleague in the Royal Infirmary, and the professor o obstetrics in the University, Dr. Simpson who says of our hospital that he "does not consider the proportion of cases excessive in an institution where one of the surgeons makes a speciality of the class of patients requiring that operation."

Yours, &c.,
Liverpool, January 20. **Francis Imlach.**

◆

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—My attention has been drawn to a statement in a letter to a Liverpool daily paper by Dr. Imlach, one of the surgeons to the Liverpool Hospital for Women in which a reflection is made on the other members of the hospital staff. As I do not consider the columns of a daily paper the proper medium for a professional discussion I respectfully ask for permission to reply in your valuable journal.

The passage to which I take exception runs as follows:—"It is useless to object to my advanced surgery whilst the hospital books show that I have subjected a smaller proportion of patients with these ailments to surgical treatment than any of my colleagues." If this passage has any meaning at all, I take it to mean that he has subjected a smaller proportion of ovary and tube cases to castration than any of his colleagues, and that the hospital books show this.

The facts of the case are as follows:—During the year 1885, 346 cases were admitted into the hospital. Of this number, 95 were under my care, 37 under the late Dr. Lupton; these numbers added together amount to 132, which, subtracted from 346 the total number, leaves 214 to be treated by the remaining surgeon. My total castration cases were 13, or 13·6 per cent. of all my cases. Dr. Lupton's were 5, or 13·5 per cent. Dr. Imlach's were 77, or 35·9 per cent.

These, Sir, are the facts and the figures, extracted from the hospital books. How Dr. Imlach arrives at the conclusion stated in the sentence quoted is not for me to say. During the past year (1886) my total castration cases have been 3 per cent. of the total treated by me in the hospital. During the last three years I have seen enough of the operation in question to become convinced that it is not the wonderful boon to womankind its advocates would have us believe, although I believe it to be of great value in properly selected cases.

I am, Sir, yours, &c.,
J. E. Burton,
Jan. 24. Surgeon to the Hosp. for Women, Liverpool.

◆

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—It is not quite easy, from Dr. Keith's letter, to see what particular operation he is referring to when he says that, "the death-rate of one woman in every twelve following an operation for a complaint that, of itself, is rarely dangerous to life, was an excessive mortality, and far more than sufficient to banish the operation from surgery altogether." As far as I can discover, he is alluding to removal of the appendages for myoma, and if this be so, I am bound to say I entirely agree with him, because if as heavy a mortality as this were to be maintained an operation which, in the great bulk of instances, is peformed for the relief of suffering and certainly not for the saving of life, would have a very strenuous argument against it.

But I think it only fair to remind Dr. Keith and your readers that the criticism which he exercises is directed against a new institution in the first year of its existence, and that the workers and workshop both being new, it is not surprising that the mortality should be somewhat heavy. That fact was the only criticism which I found I could legitimately direct against the Liverpool Hospital for Women, and you will find it pointed out in my report to the Committee. I believe that the legitimate mortality for this operation does not exceed three per cent.

I think it also fair to point out that the mortality of abdominal surgery in Liverpool until the establishment of the Liverpool Hospital for Women was something perfectly awful, a mortality which could not be justified under any conceivable circumstances; and that whatever the faults of the Liverpool Hospital for Women may have been, it certainly had this merit, that in the course of twenty-four months it reduced the mortality of abdominal surgery, so far as we know it in Liverpool, from a condition which was absolutely indefensible to one which was certainly within the limits of discussion.

I am, &c.,
Birmingham, Jan. 21. **Lawson Tait.**

◆

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In your issue of the 19th inst., you print a letter from Dr. Thomas Keith of Edinburgh which appeared in the *Liverpool Daily Post* of the 17th. It is much to be regretted that such letters should find their way into the columns of the public press. But I wish to draw attention to the last sentence "the death-rate of one in every twelve women . . was an excessive mortality, and, *far more than sufficient to banish the operation* (the removal of uterine appendages) *from surgery altogether*." I would ask how it is that a far higher mortality on their introduction has not banished many other useful operations from surgery, nor prevented a decreasing mortality from eventually raising them to the position of being a credit to surgery?

Again, I quite agree with the opinion given by Mr. Lawson Tait in your same issue, that the term Laparotomy is wrong and misleading. If it means anything it signifies a *flank* incision, and is not appliable to a central abdominal incision, *gastrotomy*, a belly incision is more correct, but as that term is now rather restricted in its significance, as hybrid terms are somewhat in vogue, perhaps *bellotomy* might be a useful introduction! Perhaps the British Gynæcological Society might turn its attention to a revision of the terms in its speciality.

I am Sir, yours, &c.,
Harley Street, London, W. **Heywood Smith.**
Jan. 21.

THE TREATMENT OF NEURALGIA BY HYDROCHLORATE OF AMMONIA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Referring to the annotation in your last issue on "A Reputed Anti-Neuralgic Specific," I wish to call the attention of my professional brethren to hydrochlorate of ammonia in this connection. I am not aware that this drug has been generally used in the treatment of neuralgic affections, but in my own practice I have by repeated trials been led to look upon it as a specific, especially in those forms of the disease affecting the dental and facial nerves. I give it in from ten to twenty-grain doses every two hours until the symptoms are relieved; but if after the patient has taken it four times, the pain continues, it will be useless to persevere. In toothache proper it is often of great benefit; however, if there be inflammation around the fangs of the tooth, hydrochlorate of ammonia will do no good. It may be administered in any convenient vehicle. I generally use either camphor or chloroform water, the latter is perhaps the better, as it somewhat disguises the excessive saltness of the hydrochlorate, the greatest drawback to its administration.

Yours, &c.,
Moira House, Peckham, **W. T. Greene, M.B., M.D.**
Jan. 20th.

◆

At the Societies.

PATHOLOGICAL SOCIETY OF LONDON.

The chief interest of the last meeting of the Pathological Society was naturally centred in the address delivered by Sir James Paget on his assumption of the presidential office, and which is elsewhere referred to in this number of the *Medical Press and Circular.* A certain amount of routine work was, however, accomplished, four communications having been read during the evening, the first being one by Mr. E. H. Fenwick on a case of Hypertrophied bladder. A frozen section of the organ was exhibited, showing the anterior wall to be twice the thickness of the posterior, a condition of things which Mr. Fenwick regards himself as being the first to observe as obtaining in these cases. He attributed the immunity from rupture enjoyed by the anterior wall of the bladder to its greater strength, elasticity, and resistance to pressure, and the fact that the condition described had hitherto escaped notice, he regarded as due to the rarity with which cases of unrelieved stricture were encountered on the post-mortem table. The novelty of Mr. Fenwick's discovery was endorsed by Sir James Paget, and as a further contribution to the discussion Mr. James Black volunteered a theory to account for the condition described.

A specimen of fatty tumour in the interauricular septum of the heart of a woman, æt. 76, was next shown and described by Dr. Handford, who mentioned that he could find but three instances of a similar growth recorded in medical literature. Even the great museums in the country do not possess an undoubted specimen of such tumours, and no description of them had been hitherto given at the meetings of the Pathological Society. The example in question was of the size of a small pigeon's egg well defined but not encapsuled, and when cut it presented all the characters of an ordinary lipoma.

Dr. Ord's was the next paper contributed, "Spontaneous Disintegration of Vesical Calculi," being illustrated by fragments of such a calculus which had been passed at intervals during six months by a gentleman, æt. 76, the subject of albuminuria and of sugar in the urine. Chemically the stone consisted of uric acid and urate of ammonia, and Dr. Ord inclined to think the occurrence of spontaneous disintegration might possibly be of comparative frequency. Sir James Paget said he had seen similar specimens.

Dr. Seymour Sharkey next read a communication dealing with a case of "Infantile Palsy" in a man, æt. 60, who died of œsophageal cancer. He had been for fifty-eight years deprived of the use of his leg, the muscles being replaced by masses of fat in which could be distinguised pinkish longitudinal streaks. The lumbar region of the end was much wasted, but in replying later to a question from Mr. R. W. Parker, Dr. Sharkey said there were no obvious changes found in the cortical motor centres. Dr. S. Wilks and Mr. W. Adams also took part in the discussion.

◆

Sir Andrew Clark, Bart., M.D., has consented to preside at the sixty-seventh annual Festival of the Seamen's Hospital Society, on February 16th.

The Lord Chancellor has, on the recommendation of the Lord Lieutenant, placed the name of Dr. Langdon Down in the Commission of the Peace for the County of Middlesex and the City and Liberty of Westminster.

Literary Notes and Gossip.

Messrs. Longmans have two books in the press by Dr. B. W. Richardson, F.R.S. "The Health of Nations," a review of the works of the veteran Edwin Chadwick, with a biographical dissertation; and "The Common Health," a volume of essays by the same distinguished author.

⁂

As extraneous to, yet as assisting their business as manufacturing druggists, Messrs. Burroughs, Wellcome & Co. have just issued for the first time, a *Medical Diary* (1887) which specially provides for all matters of interest to the general practitioner, including space for the entry of daily visits, accouchements, vaccinations, &c. The work is produced in a very convenient and portable form for the pocket in roan tuck, and the modicity of its price (2s.) must secure for it the attention of the medical public as the cheapest medical diary *extant*.

⁂

A ministerial proposal is now on foot in Austro-Hungary to bring in a bill at the next session of the Austrian Reichsrath for instituting an inspection of food and articles of domestic and other use, thus following the example of Germany and the Western States of Europe. For the purpose of aiding in this much-to-be-desired scheme a newspaper has just been founded, under the title *Zeitschrift fur Nahrungs-Mittel Untersuchung und Hygiene* (Journal for Food Inspection and Hygiene) under the editorship of Dr. Hans Heger, Editor of the weekly *Pharmaceutische Post*. We wish the new journal all the success that the very laudable object of it deserves.

⁂

A writer in *Los Avisos* mentions that a dog which had been previously twice bitten by vipers, was several times subsequently bitten by different rabid dogs, and had shown no symptom of rabies itself. He suggests the possibility of the poison of the viper having conferred an immunity from rabies. In the interests of suffering humanity, the medical portion of it in particular, we would suggest that some of our friends of the anti-vivisection persuasion might import a cargo of vipers to personally solve the problem without the necessity of experimenting on animals. The difficulty under the second head could be easily overcome, as according to their theories, a supply of rabid dogs is always at hand.

⁂

Dr. Murrell is to be congratulated on his good fortune as an author. Few, especially in medicine, have the felicity of seeing their labours so rapidly absorbed by an appreciative public. New editions of both works, "What to do in Cases of Poisoning," and "Massage as a Mode of Treatment," have been issued during the last few days, the former as a fifth, the latter a second edition, after but a few months' publication. Dr. Brunton's latest book, "Pharmacology and Therapeutics," is also a great success, a third edition having been called for. A third edition of Dr. Handsel Griffiths' "Materia Medica and Pharmacy" is also announced for this week.

⁂

The 1887 issue of the *Sanitary Record and London Medical Record Diary* fully maintains its high reputation for usefulness. The vast amount of information which it contains relating to sanitary matters and laws is certain to be appreciated by those interested in the subject. One point which attracts attention in this year's diary is the meagre list of legislative enactments bearing on public health which have been made law during the past year. This paucity results from the peculiar and almost unprecedented condition of parliamentary business rather than from any lack of subjects calling for prompt attention. There are some interesting articles and statistics bearing on the compulsory notification of diseases, the more rigid enforcement of which would, in the opinion of some authorities, do much to stamp out certain forms of disease which are still lamentably prevalent in our midst.

⁂

Dr. Bristowe has done well to republish in pamphlet form his admirable address on medical education, examination, and degrees. His opinions are those of a man who, while untrammelled by prejudices of past centuries, fully appreciates the importance of a good education. He would like to see the medical student have the education of a gentleman, not too classical, but comprising science and literature. He would like to see him able to write and speak his own language with correctness, if not with grace, and he would not think less of him if he could define the "parallelogram of forces." Idleness and desultoriness may be forgiven in the schoolboy, but in the medical student are little less than a crime. Dr. Bristowe evidently does not take too sanguine a view of the attainments of the great bulk of medical students, who scramble, he says, through their examinations with the aid of the "coach" and the cram-book, indifferent to the responsible nature of their calling.

⁂

While the author approves of the scheme for a "London M.D.," he would exact the proof of a general education superior to that possessed by the general run of men, and in this most thoughtful persons will agree with him. In other words, a degree should be a distinction, and not a qualification to practise. This, of course, is the pith of the question, and it may be observed that in every other country than our own, the doctorate is practically the only qualification to practise. To make it something more is to ratify an artificial state of things which ought long ago to have become obsolete. The M.D. degree should include surgery, which is only a department of the art of healing, and no special degree in that branch is either called for or desirable.

⁂

"I went yesterday (1848)," says Mr. Greville, in his recently published journal of "The Reign of Queen Victoria," vol. iii, p. 110, "to St. George's Hospital, to see the chloroform tried. A boy, æt. 2½, was cut for a stone. He was put to sleep in a minute, the stone was so large and the bladder so contracted, the operator could not get hold of it, and the operation lasted above twenty minutes. . . . A curious example was shown of, what is called, the *etiquette* of the profession. The operator could not extract the stone, so at last handed the instrument to Keate, who got hold of the stone; thereupon the first surgeon begged to have the forceps back that he might draw it out, and it was transferred to him; but, in taking it he let go the stone, and the whole thing had to be done over again. It was accomplished, but, not of course, without increasing the local inflammation and endangering the life of the child. I asked Keate why, when he had got hold of the stone he did not draw it out. He said the other man's 'dignity' would have been hurt if he had not been allowed to complete what he had begun."

⁂

Street's *Indian and Colonial Directory* for 1887 has just made its appearance, and its value as a work of reference has been this year increased by numerous additions. Beside the Trade Returns, Tariffs, Populations, &c., the present volume contains full particulars (with rates and times of transit) of the Steam, Postal, Parcels Post and other communications with the various places treated of; and the average time of transit by sailing vessels is also given. The latitude and longitude of all the towns, with the distances from this country, are given. The leading professional men —*e.g.*, physicians, surgeons, solicitors; the merchants and traders of every class, are fully enumerated, and concise descriptions of each country and town are furnished, with a view more particularly to show their commercial capabilities and peculiarities. Maps are again given of all the principal countries of which particulars are furnished in the letterpress. These have been specially revised for the work, with the view to show the relative positions of the chief towns, without confusing the maps with a host of names of unimportant villages and stations. To facilitate reference the names of the chief towns, the principal products of the different countries, and similar information, are alphabetically arranged.

⁂

New Books and New Editions.—The following have been received for review since the publication of our last list, December 22nd. "Text-book of British Fungi," by W. D. Hay, F.R.G.S. "Home Rule Wrinkles for Ladies," by "Aunt Betsy." "Retrospect of Medicine from July to December, 1886," edited by James Braithwaite, M.D. Lond. "Some Phases of Cerebral Syphilis," by Julius Althaus, M.D. "On Tinnitus Aurium," by Julius Althaus, M.D. "The Bovine Prescriber," by J. B. and Albert Gresswell. "Thomson's Conspectus," edited by Nestor Tirard, M.D., F.R.C.P. "Diseases of the Bones and Joints," by C. H. Macnamara, F.R.C.S. (3rd edit.) "Health atSchool," by Clement Dukes, M.D. "Annales de la Société d'Anatomie Pathologique de Bruxelles. "Antiseptic Surgery in its Application to Military Hospitals," by Surgeon-Major John Martin, Army Medical Staff. "On Massage," by W. Murrell, M.D., F.R.C.P. "What to do in Cases of Poisoning," by W. Murrell, M.D., F.R.C.P. "Researches on the Venoms of Poisonous Serpents," by S. Weir Mitchell, M.D., and E. T. Reichert, M.D.

◆

Obituary.

DR. DENHAM, OF DUBLIN.

The profession in Dublin, especially those of the obstetric speciality, were much distressed by the death of Dr. John Denham, which took place on Friday last, at his residence in Kingstown. The deceased gentleman was the son of a Presbyterian clergyman, and having served his apprenticeship to Ephraim MacDowel, began life as a public and private teacher in Park Street and the Carmichael Schools, and achieved much success, popularity, and profit. He speedily came to the front as an obstetrician, and was eventually elected Master of the Rotundo, which position he occupied for the usual period of seven years. He was for a lengthened period elected annually as a Councillor of the College of Surgeons, and he served as President in 1873. In 1885 he fell into ill-health, and retired from the profession, being then presented with a valuable testimonial by his many friends. He was a most genial and amiable man, and his patient spirit sustained him through many vicissitudes of a long life, which now ends with the sincere regrets of all who knew him.

◆

DR. ROBERT D. TANNAHILL, OF GLASGOW.

Another well-known Glasgow practitioner has passed away in the person of Dr. R. D. Tannahill, one of the oldest and most esteemed members of the Faculty of Physicians and Surgeons of Glasgow. He was a native of Kilmarnock, and being early thrown upon his own unaided resources for making his way in the world, he, by resolution and industry, soon realised the means which enabled him to enter the University of Glasgow as a student of medicine, and, after becoming duly qualified, he commenced his professional career as surgeon on board one of the first steamers that crossed the Atlantic. He afterwards settled down in Kirkintilloch, where he remained a few years. About forty years ago he removed to Glasgow, where he gradually drew around him an extensive private practice. For some years he was a visiting physician and clinical lecturer in the Royal Infirmary. He was subsequently medical attendant at the Lock Hospital, and afterwards at the Maternity Hospital. For ten years he was one of the examiners at the Faculty of Physicians and Surgeons, and latterly he held the appointment of public vaccinator at the Royal Infirmary. About ten months ago he was laid aside by a severe inflammatory attack, and although the disease was overcome he did not recover strength, and after long but painless lingering he calmly expired at his residence in Lenzie on Wednesday last, aged 76.

◆

Lecture Arrangements at the Royal College of Surgeons of England.—On reference to an announcement in our advertising columns, it will be seen that the lectures for the year will be commenced on Monday next by Mr. J. Bland Sutton with a course of three lectures on "Evolution in Pathology." Professor Francis Warner, M.D., will follow with three lectures on "The Anatomy of Movement." Professor W. H. Hylson Jessop will then deliver three lectures on "The Intra-Ocular Muscles," commencing on Wednesday, the 16th of February. Professor C. Barrett Lockwood, three lectures on "The Development and Transition of the Testicle—Normal and Abnormal," commencing on Wednesday, the 23rd of February. Professor Anthony A. Bowlby, three lectures on "Injuries of Nerves, their Pathology, Symptoms, and Treatment," commencing on Wednesday, the 2nd of March. Professor Charles Stewart, nine lectures on the "Auditory Organs of the Vertebrata," and on "Some Recent Additions to the Museum," commencing on Wednesday, the 9th of March. The course of lectures for the year will be concluded in June by Leonard C. Wooldridge, M.D., Professor Henry Power, and Professor Christopher Heath.

Society for Relief of Widows and Orphans of Medical Men.—A quarterly court of this Society was held on Wednesday, Jan. 12th. In the unavoidable absence of the President, Sir J. Paget, the chair was taken by the senior Vice-President present, Mr. Tegart. A sum of £1,364 was voted for distribution among the sixty-three widows and nine orphans on the funds. The expenses of the quarter amounted to £55 8s. 6d. One new member was elected, and the resignations of four read, and the deaths of five reported. The Secretary stated that during the last year there had been sixteen deaths among the members, and nineteen resignations, and only five elected. Astonishment was expressed by many of the directors that so few new members joined, the advantages being so great; some thought if it could be made more generally known that young men could join on completing their studies and when still living within the twenty mile radius, and that when once a member the membership was not forfeited by removal beyond the radius, or even out of the country, many young men would avail themselves of the opportunity of ensuring a slight provision for their widows and orphans.

Royal College of Surgeons of England.—The following candidates having undergone the necessary examinations for the diploma, were admitted Members of the College on Monday, Jan. 17th:—

Cranstoun, George, M.B.Durh.
Middleton, Alfred H., M.D.Dub.
Moxham, Marcus Camplin, L.S.A.
Murray, John, M.B.Dub.
Tattersall, C. Herman, L.R.C.P. Lond.
Wild, C. Henry, L.K.Q.C.P.I.

The following were admitted on Tuesday, Jan. 18th:—

Adams, Percy Targett, L.S.A.
Browne, Henry, L.S.A.
Foxton, E., M.D., Kingston.
Green, Arthur, M.B.Durh.
Harrington, S. H. N., L.K.Q.C.P.I.
Howlitt, John F., M.B.Toronto
Johnson, John G., L.R.C.P.Lond.
McLearn, Isaac C., M.D.Q.U.I.
Sparrow, John E. P., L.S.A.
Sumpter, Berners George, M.B. Durh.
Thornton, Fred. W., L.K.Q.C.P.I.
Yeoman, W. Metcalfe, M.B.Durh.

The following were admitted on Wednesday, Jan. 19th:—

Blake, William Henry, L.S.A.
Brown, Henry Herbert
Crook, Herbert E., L.R.C.P.Lond.
Duncan, H., L.R.C.P.Lond.
Spencer, George H., L.K.Q.C.P.I.
Williams, J. T. Creswick, L.S.A.

The following were admitted on Thursday, Jan. 20th:—

Hebblethwaite, Harold
Nicholson, Charles
Taylor, Frederic Howard
Green, Robert Walter
Yunge-Bateman, Marcus George
Bulgarine, Wilfred
Brown, Lewis Henry
Simpson, Charles Shackleton
Turtle, Frederick Wennan
Frost, Francis Turnor
Grose, John Sobey
Farr, Joseph James William
Hitchings, Robert
Powell, Lewis
Charles, Henry Evans
Rymer, James Francis
Beadle, Joseph.

The following were admitted on Friday, January 21st:—

Gravely, Harry, L.S.A.
Walls, James, L.S.A.
Marshall, Arthur Lumsden, L.S.A.
Walsh, Robert William, L.S.A.
Harris, Edward Bernard, L.S.A.
Helsham, Hugh P., L.R.C.P.Lond.
Blenkinsop, Alfred P., L.R.C.P. Lond.
Bidwell, Leonard Arthur, L.S.A.
Brook, William Henry Breffet
Staple, James Dibble, L.S.A.
Garrould, Walter R., L.R.C.P. Lond.
Hamilton, Robert Jessop
Bueno de Mesquita, Solomon
Williams, Arthur Henry
Crouch, Charles Percival
Corbin, E. R. St. Clair, M.B.Lond.

The following were admitted on Monday, Jan. 24th:—

Ford, Theodore Albert V., L.S.A
Abbott-Anderson W. M., M.B.
Browne, E. G., L.R.C.P. Lond.
Fitzgerald, Gerald C., M.B. Camb
McShane, George, L.R.C.P. Lond.
Evelyn, W. A., L.R.C.P. Lond.
Cook, Edward Thomas, L.S.A.
Bullock, Roger
Loxton, W. A., L.R.C.P. Lond.
Kitson, F. P., L.R.C.P. Lond.
Taylor, John Francis, L.S.A.
Hamel, Julius
Greene, Henry Bertram Blodwell
Brownfield, Harry Munyard
Duncker, W. R., L.R.C.P. Lond.
Hicks, Edward Harmam, L.S.A.
Evans, Howell Thomas
Griffiths, William, L.S.A.

King and Queen's College of Physicians.—At the January examinations the following obtained the licenses in Medicine and Midwifery of the College:—

Medicine.

Campion, Thomas Spread
Haslop, William H.
Hughes, Hugh Griffith
Mathews, Henry John
Monsell, Frederick William
O'Loghlin, Denis Joseph
Parry, Thomas Fox
Sclesfield, John
Wilson, Thomas Henry.

Midwifery.

Campion, Thomas Spread
Connellan, Thomas Augustus
Corkery, Timothy
Hughes, Hugh Griffith
MacFeeters, Wm. Edward
Mathews, Henry John
Monsell, Frederick William
O'Loghlin, Denis
Parry, Thomas Fox
Wilson, Thomas Henry.

The following were admitted Members of the College:—

Hanrahan, J. Armstrong
Frazer, William
Frazer, William (Dublin)
Nugent, Guy, P. L'E.

Notices to Correspondents, Short Letters, &c.

☞ **CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attenion to this rule.

DR. ILLINGWORTH (Clayton-le-Moors).—If possible in our next.

MR. C. H. W. (Devon).—Better late than never.

PROFESSOR CHARCOT is thanked; his lecture will appear in an early number.

MR. J. D. H.—So peculiarly local, and of interest to no one in the profession outside the limit. Sorry we cannot devote space to it for these reasons.

DR. J. S. S.—Not a very reliable test. We would advise you to get Oliver's little book; the instructions are simple and precise, and you would get a more satisfactory result.

AN INTENDING EMIGRANT.—Yes; we believe you are right about the P. and O. Company being the dearest line. A few days since we were assured by a young practitioner—who is quite as impecunious as yourself, and who intends to practise in India as a civil surgeon—that he had made inquiries into the matter of all the several companies, and found that the Austrian Lloyds answered his requirements the best. They engage to send him and his wife, second class rail and first class boat, from London to Bombay, *vià* Trieste or Brindisi, for £50 each, and they allow him a choice of eight different railway routes to either of these places. So that if you go by their line you can travel either by Madrid or St. Petersburgh, Vienna or Paris, &c., &c., and you will have, in addition, a bottle of wine at both your principal daily meals. The Rubattino Company is equally cheap, but the cooking—Italian—is not so good. Another decided advantage is that these companies make no charge for a reasonable excess of luggage. There is also less restraint on board them than there is on the steamers of the P. and O. Co.—the captains of which are apt to give or assume for themselves *novel* airs and ideas. We are happy to be in a position to give you this advice.

AMATEUR.—1. We do not remember the writer's name, but this is probably what you want:

Thrice happy race! that innocent of blood,
From milk innoxious seek their simple food.

2. Fitzgerald's Glossary of Botanical Names.

THE DIET OF CENTENARIANS.

A **WRITER** on this topic holds in a contemporary that "the rules of life laid down by Cornaro are probably perfect," and he intimates that, in his opinion, "twelve ounces of solid food and sixteen ounces of liquid appear to be the maximum requirements of age." The solids ought, he thinks, to be made up of one-third animal food, chiefly flesh, and two-thirds vegetable nourishment. He dislikes fruit and fish, and says that salt and sugar should only be used sparingly. He also deprecates the too copious use of milk as well as of drugs, and after adding that industry of some kind should be practised, he gravely points out the valuable medicinal properties of port wine. The latter is certainly more suited to advanced life than is almost any other form of stimulant.

TYRO.—As you profess to have made your discovery out of very simple materials and in rather a primitive way, you might do worse than usher it into life under the auspices of the following:—

The invention all admired, and each how he
To be the inventor missed, so easy it seemed
Once found, which yet unfound most would have thought
Impossible——

CHLORODYNOMANIA.—Yes; and a husband lately complained at the Westminster Police Court that his wife, aged thirty, would drink three or four bottles a day of chlorodyne. She was, he alleged, entirely destroying her own mind, and ruining him in pocket. She had spent as much as six shillings a day on the purchase of this compound, and there is no doubt but that "manias" of this kind are on the increase amongst us.

AGRICOLA.—Your criticisms are too one-sided to be relevant or even coherent, and you should remember the dictum of the late Chief Justice Whiteside, that "the condition in which a foreign people live, in regard to the enjoyment of political or even personal liberty, is felt and understood by the stranger, only by degrees, and after some lapse of time."

Meetings of the Societies.

WEDNESDAY, JANUARY 26TH.

HUNTERIAN SOCIETY.—At 8 p.m., Mr. Croft will explain and demonstrate the Method of Treating Fractures by the Immediate Application of Plaster-of-Paris.

BRITISH GYNÆCOLOGICAL SOCIETY.—At 8.30 p.m., Specimens will be shown. Address on Listerism, by Dr. Granville Bantock. Council at 8 p.m.

THURSDAY, JANUARY 27TH.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—At 8.30 p.m. Living and Card Specimens at 8 p.m.:—Mr. Nettleship: (1) Atrophy of Optic Nerves with Multiple Congenital Exostoses of Skull; (2) Three Cases of Night Blindness with Peculiar Retinal Changes.—Mr. George Cowell: Three Cases showing the result of Operation for Conical Cornea.—Mr. Marcus Gunn: Case of Transverse Calcareous Film of Corneæ. Papers:—Mr. P. H. Mules: A short record of Some Unusual Clinical Cases. Mr. G. A. Berry: On three cases of Acute Cerebral Disease with Ocular Symptoms. Mr. W. H. Jessop: Sudden and Lasting Lateral Nystagmus. Mr. W. Lang: Case of Meningitis after Excision.

FRIDAY, JANUARY 28TH.

CLINICAL SOCIETY OF LONDON.—At 8.30 p.m., Address by the President. Mr. Henry Morris: (1) A Case of Calculous Disease of both Kidneys, with Remarks on the Surgical Treatment of Calculous Kidneys; (2) A Case of Nephro lithotomy. Mr. Howard Marsh: A Case in which very Severe Symptoms were due to Four Small Stones in an Atrophied and Movable Kidney; Failure to Detect the Kidney by Lumbar Incision; Discovery by Laparotomy; Successful Removal of the Organ. Mr. W. H. Bennett: A Case of Supposed Nephrotomy for Scrofulous Disease. Living Specimens: Mr. J. R. Lunn: (1) A Boy with Ichthyosis; (2) Peculiar Deformity of the Feet in an Ataxic Patient; (3) A Man with Raynaud's Disease of the Feet; (4) A case of Myxœdema with want of Development of the Genital Organs.

ACADEMY OF MEDICINE IN IRELAND.—The Medical Section will meet in the College of Physicians at 8 p.m. Living specimen (Dr. Knight): A Case under Treatment by Massage. Manipulations shown by an experienced Masseur. Papers—Dr. Conolly Norman: Variations in Form of Mental Affections in relation to the Classification of Insanity. Dr. J. Molony: Short Notes on Cases of Insanity. Dr. Knight: A Note on the Prevention and Treatment of Disease.

Vacancies.

Brompton Consumption Hospital.—Resident Clinical Assistants. Applications to the Secretary before Feb. 19th (see advert.).

Hull and Sculcoates Dispensary.—House Surgeon. Salary, £150 per annum, with house (unfurnished), coals and gas. Written applications, with testimonials, &c., must be forwarded on or before the 1st February to the Honorary Secretary.

The Great Northern Central Hospital, Caledonian Road, London, N.—Surgeon. Applications, with testimonials, to the Secretary, on or before Jan. 29th.

National Orthopædic Hospital for the Deformed.—Surgical Registrar and Anæsthetist. Honorarium, £20. Applications, with testimonials, to the Secretary not later than the 1st February next.

Jaffray Suburban Branch of the General Hospital, Gravelly Hill, near Birmingham.—Resident Medical Officer. Salary, £150 per annum, with board, residence, and washing. Applications, with testimonials, to the House Governor, on or before the 29th January.

North Riding Infirmary, Middlesbrough-on-Tees.—House-Surgeon. Salary, £100 a year, with bed, board, and washing, and £5 a year in lieu of beer. Applications to the Secretary not later than February 2nd.

Appointments

BRIGGS, H., M.B., F.R.C.S., Honorary Medical Officer to the Hospital for Women, Shaw Street, Liverpool.

BURKITT, J. C. S., M.D., L.Ch. Roy. Univ. Irel., Medical Officer to the Whitwick Local Board.

CASTLE, H., M.B.Lond., M.R.C.S., Medical Officer for the Shorwell North District of the Isle of Wight Union.

COURTEES, R., M.B.Durh., M.R.C.S., Assistant Medical Officer to the St. Marylebone Infirmary, Notting Hill, W.

GREENLEES, T. D., M.B.Edin., Assistant Medical Officer to the City of London Asylum, Stone, Dartford.

HOBBES, T. G., F.R., L.F.P.S., L.M., Medical Officer and Public Vaccinator to the Sutton District of the Aston Union.

INGLEBY-MACKENZIE, K. W., M.R.C.S., L.R.C.P.Lond., House Surgeon to the Royal Isle of Wight Infirmary, Ryde.

JOLLIFFE, W. J., M.R.C.S., L.R.C.P.Ed., Medical Officer for the Shorwell South District of the Isle of Wight Union.

RYGATE, J. R., L.K.Q.C.P.I., L.R.C.S.Ed., Medical Officer for the Seventh District of the Bridgwater Union.

WESTON, G. H., M.R.C.S., L.S.A., Medical Officer for the Polesworth District of the Atherstone Union.

WHITFORD, W., M.D., Physician to the Stanley Hospital, Liverpool.

Births.

ADAMS.—Jan. 20, at 1 Clifton Gardens, Kensington, the wife of G. D'Arcy Adams, M.D., of a son.

HERMAN.—Jan. 19th., at 20 Harley Street, London, W., the wife of G. Ernest Herman, M.B., F.R.C.P., of a son.

HUNT.—Jan. 19, at Crouch Street, Colchester, the wife of Edgar A. Hunt, M.R.C.S., L.R.C.P., L.S.A., of a daughter.

Marriages.

DAVISON—GELL.—Jan. 20, at St. John's, Fitzroy Square, London, Charles Davison, M.D.Ed., of Paris, to Jessie Elizabeth, widow of Thomas Silvester Gell, M.D.Ed., of St. John's Lodge, Kensal Green.

WARNER—GROVE.—Jan. 19, at St. Peter's, Eaton Square, London, S.W., F. Ashton Warner, L.R.C.P., M.R.C.S., to Syndney Anne, daughter of the late Christopher Grove, of Hertford House, Bucks.

Deaths.

ANGIER.—Jan. 16, at his residence, Upper Norwood, James Hague Angier, M.R.C.S., L.S.A., in his 84th year.

DENHAM.—Jan. 21st, at 7 Clarinda Park, Kingstown, John Denham, M.D., aged 81.

HANAN.—Jan. 17th, at Tallow, co. Waterford, William Hanan, Esq., M.D., L.R.C.S.Edin., aged 84.

HOLLIS.—Jan. 17th, at Deacons, Yarmouth, Isle of Wight, Charles Wise Hollis, M.D. Univ. Edin., in his 71st year.

NOTT.—Jan. 17th, at Russell Road, Kensington, Hamlin Nott, M.R.C.S., L.R.C.P.Ed., Surgeon-Major H.M.'s Indian Forces.

SNAPE.—Jan. 13th, at Chorley New Road, Bolton-le-Moors, Richard Forth Snape, F.R.C.S.Eng., aged 65.

IRISH POOR-LAW INTELLIGENCE.

◆

CAVAN UNION.

THE OFFICERS' SALARY.

Mr. Elliott moved—"That all officials of this Union whose income exceeds £52 per year be reduced 25 per cent." He said that from the action of that board in the past, he found it expedient to bring on this notice of motion. A number of guardians had formed themselves into a committee—he would call them nothing else than a "taxing commiteee"—to heap up the salaries of all the union officials, and he thought that he wouldn't be doing his duty to his constituents if he, for one, didn't raise his voice against the system. There was widespread agricultural and commercial depression over the whole country.

Mr. Boland—Supposing Mr. Elliott got his notice of motion carried twenty times, the Local Government Board would never sanction it; and I now move that the salaries of the officials stand as they are.

Mr. Elliott—I see a lot of strange guardians here to-day—*ex-officios*—and I would like to know if they have their credentials with them?

Mr. Faris—Does Mr. Elliott's notice of motion extend to the doctors.

Mr. M'Cabe—Certainly.

Colonel Saunderson, M.P., said that all things had gone down lately—landlords' rents were lessened, and prices for produce were depressed; and he believed that official salaries should go with the times and also be reduced; the only difficulty he found was to come to a proper understanding how much the salaries should be brought down.

The Clerk—In an Arva case, the Local Government Board refused to sanction the reduction of an officials salary.

Mr. A. E. Humphrys—I am not in favour of keeping up taxation, but I think the officials of this union do their work to the satisfaction of all, and I don't see why their salaries should be reduced. We all know the amount of work gone through by our clerk; and I for one don't think his salary a bit too high.

Colonel Saunderson, M.P.—I move as an amendment to Mr. Elliott's notice of motion, "That in the opinion of the board the salaries of all officials in the Union be reconsidered, with a view to reduction, and that we ask the opinion of the Local Government Board on the matter."

Voted for Mr. Elliott's motion, 22; for Mr. Boland's amendment, 11.

The Chairman declared Mr. Boland's amendment beaten; and on another division being taken, the following voted—

For Colonel Saunderson's amendment, 16; for Mr. Elliott's motion, 19.

The Chairman declared Mr. Elliott's motion carried.

◆

REDUCTION OF POOR-LAW SALARIES IN IRELAND.

I. I. I. asks 1. Can the Board of Guardians bring forward a motion and pass it, reducing the dispensary medical officer's salary without consulting the Dispensary Committee?

Yes, the assessment of salaries lies with the guardians not with the Committee.

2. Will the Local Government Board sanction the action of the guardians in reducing the present salary of the union officers by twenty-five per cent.?

[We hope and believe not unless some very forcible reason can be shown. They have generally refused sanction on the very proper ground that the salary upon which officers are dependent ought not to be an uncertain quantity, and that they suffer more from depression of business than anyone else. Our correspondent should at once write a strong appeal to the Local Government Board.—Ed.]

◆

IRISH MEDICAL ASSOCIATION.

REPORT OF THE PROCEEDINGS OF THE COMMITTEE OF COUNCIL, FROM 8th JUNE TO 21st DECEMBER.

Submitted to Council on 21st December, 1886.

Dr. J. Wallace Boyce (of Stillorgan), Chairman of Council, in the Chair.

Mr. Chairmen and Councillors.—The Committee of Council have to report that since the Annual General Meeting held on the 7th June last, they have held fifteen meetings, eight new members have been elected, ten resignations have been accepted, and three members have died. The period referred to includes the usual summer recess, which accounts for the small number of meetings.

Medical Acts Amendment Bill.

The Medical Acts Amendment Bill of 1886 has become law, but its provisions are disappointing inasmuch as they fail to protect the profession against practice by unqualified persons, and perpetuate an excessive and unnecessary number of licensing bodies granting qualifications to practice, of diverse educational grades, and without any settled standard of competency.

The Committee of Council, however, congratulate the profession on the fact that such questions as have been settled by the Act, have been settled in conformity with the principles adopted, and reiterated in years past, by this Association.

An immediate effect of the change of law has been to induce the Irish colleges of physicians and surgeons to join together for the purpose of granting a triple diploma in medicine, surgery, and midwifery; and the Committee of Council have reason to believe that the elaboration of a scheme for this purpose, by a combined committee of the two colleges, is far advanced. The scheme will enable the Irish student to obtain by one series of examinations, not much more onerous than those now required by either colleges, the complete qualification to practice in the three essential subjects, and at less expense than that heretofore required, an arrangement which is expected to prove very satisfactory.

It has been learned from the recent proceedings of the General Medical Council, that the Apothecaries' Company of Ireland has not been admitted to co-operate in this conjoint examination, though willing to give its aid towards the granting of a complete truine diploma; and that it has, therefore, claimed the right to issue a separate registrable diploma, with the assistance of coadjutor examiners appointed by the Medical Council as provided by the Act. The Committee of Council are of opinion that any arrangement which would thus further increase the number of qualifying bodies by enabling the Apothcaries' Company to issue separate licences to practice (upon educational and monetary terms as yet unknown to them), would be greatly to be deplored, inasmuch as it would increase the difficulty of keeping the standard of professional competency up to a sufficiently high level, but they hope that this objectionable arrangement may yet be averted.

The recent election of a direct representative for Ireland, under the provisions of the new Act, took place last month in accordance with the regulations previously promulgated by the Privy Council, and under the direction of Sir Henry Acland, as returning officer. The election was conducted by means of voting papers sent to every registered practitioner whose name was on the Medical Register as a resident in Ireland, and the voting paper was to be marked with the vote, and returned to the office of the Branch Medical Council in Dublin. From the official declaration of the poll the Committee of Council have learned that 2,671 such papers were issued to Irish addresses, and that 2,040 votes were returned, from which it appears that 76 per cent. of the profession in Ireland recorded their votes, a very much larger proportion than in either England or Scotland. The Committee of Council are gratified to observe that the profession has evinced so lively an interest in the election of their own spokesmen in the Medical Council, but they understand that the best sources of information have estimated the number of registered practitioners, *actually resident in Ireland,* to be very much less than 2,671; and that it must therefore be assumed that a considerable number of the recorded votes were given by practitioners who, though *registered* as at an Irish address, are, in fact, not now resident in Ireland, or materially interested in Irish medical affairs; while, on the other hand, many practitioners resident in Ireland were not in a position to receive voting papers, their addresses in the Medical Register being inaccurate.

The result of the election has been the return—as Direct Representative—of Dr. George Hugh Kidd, an ex-President of the Royal College of Surgeons in Ireland, as well as of this Association, and a gentleman whose high character as an educationalist, an obstetric surgeon, and a man of liberal views and great energy, give promise of his being a representative entirely worthy of the charge committed to him, and likely to do honour to the choice of the profession in Ireland.

It is announced that the General Medical Council will meet in February next to debate the conjoint schemes for examination, and on the 30th of June the Act will come into its full operation.

PRISON SURGEONS—ABOLITION OF OFFICE.

It has been reported to the Committee of Council that the authorities have seen fit to reduce the status of some of the Irish prisons, and amongst them that of Omagh Gaol, which recently has been converted into a Bridewell, the result of which was, that all the officers were called upon to retire on pension. Dr. Edward Thompson, surgeon of the gaol remonstrated at his being retired, inasmuch as the gaol was not to be closed, and he has held much correspondence with the General Prisons Board and the Lords Commissioners of Her Majesty's Treasury, without however producing a satisfactory result, at least, so far; and he communicated to the Committee of Council the details of his grievances, which very clearly proved that he had not been dealt with, as regards the amount of pension offered to him, according to the same scale as other retired prison surgeons, whose length of service and all other matters for consideration were identical. Accordingly at Dr. Thompson's request, the Committee of Council addressed the Lords Commissioners of Her Majesty's Treasury on the subject, and the following is a copy of a letter, to which, however, neither a reply, nor even an acknowledgement of its receipt, has yet been made, viz. :—

15th November, 1886.

TO THE LORDS COMMISSIONERS OF HER MAJESTY'S TREASURY.

MY LORDS,—The attention of the Council of the Irish Medical Association has been directed to the compensation allowance granted by your Lordships to Dr. Thompson, late medical officer of Her Majesty's Prison at Omagh, and I am directed to point out that there seems a great difference in the awards of the pensions granted to him and to the other officers of the Irish prisons, who, like him, have been compulsorily retired on abolition of office, in so far as has been represented to the Council.

In February last, it appears that Dr. Middleton of Mullingar, was pensioned, and that he received for his three and a half years' service under the Board of Superintendence £5 1s., and for his service under the Prisons Board £33 5s. 8d., while Dr. Thompson's period and conditions of service (they both having been infirmary surgeons as well as gaol surgeons) were exactly similar in every respect. It appears also to the Council that Dr. Thompson has been granted no pension for his county service of three and one third years, and only £22 10s. for the period while he was under the control of the Prisons Board.

Again it appears that the Protestant Chaplain of Omagh Gaol served the County 16 years, and the Prisons Board eight and one-third years, while the pension granted to him was £12 and £27 6s. 8d. respectively. Furthermore, the Roman Catholic chaplain of the same prison, it appears, served the Board of Superintendence eleven years, and the Prisons Board eight and one-third years, and his pension is £9 and £32 13s. 4d. Other examples of relatively similar treatment accorded to retired Irish prison officers could be detailed; but probably sufficient have been already selected to show the great difference in the rate of pension awarded to Dr. Thompson when contrasted with the retiring allowances of Dr. Middleton, and the two chaplains of the same prison with which Dr. Thompson was also connected officially.

The Council of the Irish Medical Association appeal to your Lordships with every confidence, and expect a just review of all the circumstances they have detailed, and they respectfully desire to remind your Lordships that Dr. Thompson's period of service of close upon 12 years, deserves and should receive, the most favourable consideration. They understand that he devoted himself with zeal and attention to his duties which were most responsible and arduous, and under the circumstances it seems to them a somewhat unjust and unmerited slur that he should have been awarded a lower rate of pension than the two chaplains of the prison; not to mention many instances of other officers (whose duties were light and easy in comparison with those of the medical officer) who, nevertheless, for exactly the same period of service under the Prisons Board, were awarded on retirement nearly double the amount granted to Dr. Thompson. One of the objects of the Irish Medical Association is to protect in every way the interests of the medical profession in Ireland, and the Council trust your Lordships of Her Majesty's Treasury will revise the retiring allowance granted to Dr. Thompson of Omagh, and not leave the Council one further apparently unjust matter and great grievance to be redressed.

Your Lordships most obedient servant,

ROBERT BROWNE,
Hon. Sec. to Council.

As regards the point of tenure of office raised by Dr. Thompson, and whether the authorities had a legal right to retire him on pension, merely because the status of the prison had been reduced—the prison itself not having been closed, and the services of the medical practitioner as a matter of fact, having since been from time to time required—the Committee of Council at his request submitted the case for opinion of Counsel (Mr. Ball), specially directing his attention to the 27th clause of the General Prisons (Ireland) Act, which appeared to reserve to all existing officers, previous to the passing of that Act, all the rights and privileges which they had previously possessed, one of which apparently was tenure of office for life. Mr. Ball's opinion, however, was adverse to Dr. Thompson's views; nevertheless the Committee of Council consider that Dr. Thompson unquestionably has not been dealt with as favourably as other retired prisons surgeons, and, they are of opinion that, if necessary, further steps should be taken to endeavour to obtain for him, at least as reasonable consideration by the Lords of the Treasury as was given under like circumstances to other retired prison surgeons.

POOR-LAW MEDICAL OFFICERS' SUPERANNUATION.

The Committee of Council in a short time hope for the favour of an interview with the Right Hon. Sir M. E. Hicks Beach, with a view of again bringing under his official notice, the very unsatisfactory state of the law regarding superannuation, more especially of worn out medical officers, in Ireland. Owing to the injustice of the present voluntary system, it is out of the question to obtain due and satisfactory recognition of the services of many medical officers, who, though quite unfit for their work, are compelled, throught want of other means of support, to hold office, much to the detriment of the sick poor who require the services of an active medical officer.

Upon a former occasion when this subject was brought under the notice of Sir M. E. Hicks Beach, he gave it considerable attention, and doubtless he, as well as the corresponding representatives in Ireland of other governments, all of whom in due turn have been approached by this Council, would most willingly (were it then possible), have rectified the faults of the present system. The Committee of Council look forward with much confidence to his making an early and determined effort to have the law amended, and they are led to form this opinion in consequence of the earnest consideration he gave to the subject, when a deputation from this Association brought it specially under his notice during his previous chief secretaryship.

It will be remembered that the Bill drawn up by this Association would assuredly have been passed by Parliament but for the persistent opposition of some Irish members, which on the next occasion of its introduction it is to be hoped, may be either abandoned or otherwise overcome.

The Committee of Council have every reason to hope that a Bill to satisfactorily amend the law of superannuation will at least, be introduced early in Parliament, and it will be their pleasure, as well as their duty, to do their utmost to secure its enactment.

FEES TO MEDICAL WITNESSESS AT COURT.

The Committee of Council have pleasure in reporting further cases of successful applications by medical witnessess at court, for more equitable fees and expenses, than allowed by the rules of the Committee of Judges, who were authorised to fix them, and against which it will be recollected this Association firmly protested, at the time, owing to their utter inadequacy.

At the present Sligo Assizes Dr. Caldwell of Virginia and Dr. Dundas were summoned as crown witnesses, and they applied through their Counsel for more equitable remuneration than that fixed by rule, when Chief Baron Palles ordered that there should be paid three guineas a day each, together with one guinea a night for hotel charges, besides the actual cost of their travelling expenses; these sums were ordered to be paid by the treasurer of the county in which the assault was committed.

SERVICES UNDER LABOURERS' ACT.

The Committee of Council after having given full information to Dr. Keers of Dirraw, (a member of this Association), respecting his claim for remuneration for inspection of labourers' dwellings now beg to present a report of the legal proceedings of the case, which show that a satisfactory termination was the final result (heard by David Ross, Esq., Q.C., Recorder of Belfast), viz.:—

Dr. S. B. Keers, medical officer of the Dirraw Dispensary District, in the Ballymoney Union, processed the guardians of the Ballymony Union for £5 10s., for duties performed under the Labourers' (Ireland) Act, in inspecting and writing out a report on twenty-two separate houses belonging to the agricultural classes, for which he charged at the rate of 5s. per house.

Mr. R. C. Martin, appeared on behalf of Dr. Keers, and Mr. T. M. Greer represented the Board of Guardians.

Mr. Martin, in opening the plaintiff's case, read the several acts of parliament, referring to the medical officer's duty under the Public Health Act. He also read the Labourers' Acts of 1883 and 1886.

After some further legal arguments—

Dr. Keers was examined by Mr. Martin and deposed to having visited the several houses in the Dirraw Dispensary District, in compliance with a resolution passed at a meeting of the Ballymoney Board of Guardians, and he was cross-examined by Mr. Greer.

Mr. James M'Henry, one of the guardians of the Dirraw division, deposed that in his moving at a meeting of the Board of Guardians that Dr. Keers should be paid £2 12s., he considered that amount quite sufficient for all the work he had performed.

His Honour here mentioned that he would reserve his decision until the morning, and requested that all the papers should be handed up to him, which accordingly was done.

On Saturday the Recorder delivered his decision. He said the question raised was whether the plaintiff, as medical officer of health was bound to perform the duties required of him by the defendants in reference to proceedings under the 11th section of the Public Health Act of 1878, or whether he was entitled to additional remuneration for work done under the Labourers' Act. The case for the plaintiff had been very ably argued by Mr. Martin, and having considered the statutes and decisions, he had come to the conclusion the plaintiff was entitled to a decree, and as the fees sued for were moderate, he would grant the full amount claimed.

Inquiry under Labourers' Act.

In April last, two members of this Association were officially summoned to attend and give evidence at an inquiry, under the provisions of the Labourers (Ireland) Act, held at Oldcastle, which is six miles distant from their respective residences, and they had to attend all day for three days in succession, for which they each claimed three guineas a day; but the guardians of the union declined to award more than one guinea a day to each of them. These facts were communicated to the Committee of Council, who recommended that an appeal to the Local Government Board should be made, inasmuch as that board was, by the 7th section of the Labourers' Act, invested with the power of fixing the amount of remuneration to be paid to all persons on such occasions. But it appears that one of the members referred to had previously, under similar circumstances, appealed to the Local Government Board, and had been informed that the Board would not interfere in the matter; these two members therefore under the circumstances, wisely adopted another course, and processed the Oldcastle Board of Guardians to the Quarter Sessions at Kells, where they recovered two guineas a day each for their attendance and evidence, and ten shillings a day each for their travelling expences, together with their costs. It appears that a report of this Council, dealing with such claims, was produced in court, viz., the appeal case of Rogers *v.* Youghal Guardians, and, that upon careful perusal of it, Mr. Fitzgerald, the County Court Judge, who presided at the Quarter Sessions, gave his decree ultimately in favour of the two members of the Association referred to.

Dispensary Medical Officers' Substitutes.

The Committee of Council have to report that the question, as to who is bound to pay the substitutes of dispensary medical officers does not even yet appear to be sufficiently understood, notwithstanding the issue, by this Association, of a special circular affording full instructions on the subject. The Committee of Council deem it, therefore, advisable again to revert to the matter, especially as they have lately received several communications respecting it from members of the Association, and also as a change has been made in the last issue of dispensary regulations.

The Committee of Council desire to point out that Article 22 of the Dispensary Regulations provides, "If a medical officer of a dispensary district be temporarily incapacitated by illness *or other cause*, from performing his duties, he shall immediately, if practicable, communicate with the chairman or honorary secretary of the committee, and shall if possible, reccommend to the committee a medical practitioner (fully) qualified to perform his duties during such temporary incapacity."

It is quite right and reasonable that when a dispensary medical officer becomes temporarily incapacitated by *illness* from performing his duties he should, when notifying same to the chairman or honorary secretary of his dispensary committee, send in a medical certificate to the above effect; but he is not to ask for leave of absence (or, in other words, permission to be ill!) as is often done under such circumstances.

In like manner if a medical officer be temporarily incapacitated from performing his duties by reason of *any other cause than illness*, such for instance as his being obliged to attend at court upon a *subpœna*, or his being beyond his own control, obliged officially to perform duties which would preclude him from punctually discharging his dispensary duties; he is bound, if practicable, at once to inform the chairman, or hon. secretary of his dispensary committee of the fact (stating the grounds, of which he can, when necessary, produce proof), when recommending a duly qualified *locum tenens*. In any case of *unavoidable absence* it is of course not necessary to ask for leave of absence to enable him to do that which he cannot avoid doing, viz.: in case of illness—remaining at home; or in the case of a *subpœna*—attending at court; but in either case it is reasonable that documentary proof of such obligation should be producible.

In such cases the dispensary medical officer ought to recommend or suggest as his *locum tenens* the name of a fully qualified medical practitioner, who he believes to be willing and competent to perform the duties satisfactorily; but he should take care not to enter into any arrangement whatsoever regarding the remuneration to be paid to such *locum tenens*. The Dispensary Committee have a right to select any fully qualified medical practitioner as *locum tenens* (not necessarily the one recommended by the medical officer), and the matter of his remuneration should be left altogether to him and to them. For unless the medical officer himself assents to such an arrangement no order of the Committee or Board of Guardians can compel him to pay for the services of the *locum tenens* in cases of *unavoidable absence.*

In cases of *voluntary absence from duty* the matter is quite different; the medical officer would require to obtain leave of absence beforehand on such occasions, and might or might not be required to provide the amount of remuneration to be paid to his substitute. In cases of *unavoidable absence* of a dispensary medical officer, the substitute appointed should take especial care not to accept office or enter upon the duties until he has had a clear and distinct agreement *in writing* regarding his remuneration to be paid by the Board of Guardians, and upon his appointment under such circumstances he would act prudently in informing the Committee that he declines to accept any responsibility, or to do any work until his remuneration is guaranteed. In some instances Dispensary Committees (not knowing their powers) have said that "the question of remuneration, *if any*, rests altogether with the Board of Guardians, who in a few days, will deal with it," but no such answer should satisfy the substitute. The Committee have the power to fix the remuneration (which is usually at the rate of three guineas a week), and the guardians can be compelled to pay any and every reasonable monetary agreement which a Dispensary Committee enters into—at least until they repudiate liability; and then at once the substitute, taking care to inform himself of the guardians' views, should give notice to the representative of the Committee with whom he has been in communication, that in consequence of the guardians' repudiation of liability to pay him, he there and then declines to act further, and that he will, if necessary, proceed at law, to recover the amount due to him for the time he has actually discharged the duty. Such a course of action would soon bring guardians and Dispensary Committees into a proper position, for they are bound to provide medical attendance for the sick-poor; and consequently must arrange with some fully qualified practitioner to do the work—a matter which need not perturb the mind of any medical officer who is *unavoidably* on account of illness, or other sufficient cause, absent from duty, and who has not failed to notify same as prescribed (in article 22) while being able to produce documentary evidence of the fact.

(*To be continued.*)

◆

Last week the election of a medical officer for the Monaghan dispensary, in room of the late Dr. Woods, was held, at the Dispensary House, when applications from the following, were submitted to the committee:—Dr. Devlin, Belfast; Dr. Buckley, Dublin; Dr. Shaw, Islandmagee; Dr. Webb, Dublin; Dr. J. J. A. Ireland, Lanesborough; Dr. Henry Peyton, Scotstown; Dr. Cochrane, Boyle; Dr. J. Trimble Elliott, Smithboro'; Dr. Swan, Monaghan; Dr. Henry, Monaghan; and Dr. Stewart, Glasslough. Dr. Walter Swan was elected by a majority of six votes.

THE

Lettsomian Lectures

ON

SOME OF THE MENTAL AFFECTIONS OF CHILDHOOD AND YOUTH. (a)

By J, LANGDON DOWN, M.D. Lond., F.R.C.P.,
Senior Physician to the London Hospital.

ABSTRACT OF LECTURE III.

INFANTILE mania is not of frequent occurrence and has not been the subject of much comment. Nevertheless very well-marked examples have come under my notice in quite young children; cases where the various phases of insanity in the adult have been well represented; acute maniacal attacks, in which the patient tears and destroys everything within reach, or creeps under tables and sofas to hide, screaming with undisguised rage and biting and scratching anyone who approaches. This attack subsides and the boy behaves as nicely and intelligently as possible, but in a few days has a recurrence with as great violence as before. Some few years since a little boy of this class was sent to me. He was by no means deficient in mental acuteness, in many respects was precocious; he was an only child, and having lived a good deal with adult people he talked rather sagely, but he was liable to attacks of acute mania of a very marked kind. There were no bounds to his petulance and violence. He would attack his father in the street and behave in all respects in an insane manner, regardless of any injury he might inflict, even on those for whom he ordinarily entertained affection. In the intervals of the paroxysms he manifested traits which made him much liked by those about him.

Occasionally I have met with cases having well-marked delusions of suspicion. The ordinary trust and unsuspiciousness of childhood has been replaced by painful mistrust. In one case the child imagined that he was watched and that someone was listening at the key-hole. Another had delusions that things were mixed with his food and had evident fear of being poisoned. I have seen some cases of melancholia associated with manifest delusions, one boy believing that he resembled an animal and frequently looking into the mirror to confirm or dissipate the conviction; another believed she would break if you touched her, and the fear of falling to pieces like a fragile piece of glass was a real terror to her. I had some years since under my observation a girl who, when eight years of age, put her baby brother on the fire so that he was dreadfully burnt. The girl herself was ill-favoured in appearence and she had been accustomed to hear the beauty of her brother injudiciously praised. In a maniacal attack she attempted to get rid of the subject of so much laudation. About three years subsequently she became epileptic and again later on the subject of epileptic dementia. It is highly probable that the maniacal paroxysm which manifested itself in homicidal mania was really masked epilepsy.

As puberty approaches attacks of mental aberration assume a special character; there is frequently unnatural introspection and a critical hyper-conscientiousness becomes prominent. I have recently had five cases under my care, three boys and two girls. They have all had characters much in common, they have all been very good and studious children, but between eleven and thirteen years of age have become moody, have had conscientious scruples as to their motives, have been anxious not only as to whether they had told the truth, but whether when having told it, they have done so in such a way as to convey to others the precise idea in their minds. They have had morbid views as to the standard of right and wrong; sometimes they have detailed things in a nonsequential way. One boy was troubled when he saw a dirty beggar-man or boy lest he should contaminate his mother by thinking of her immediately afterwards. I saw him greatly perturbed one day from having seen an errand-boy come to the school-house, and his thoughts flitting to his mother he was rendered inexpressibly miserable lest he had lowered, injured, and contaminated her by unwittingly thinking at the same time of her and the dirty boy. I have sometimes known an avoidance of anything positive in assertion lest the exact truth should not be spoken, so that all the replies are, "Perhaps it was," "It may have been," "I may have done so and so" about things in which no principle was involved, but from a morbid fear of not saying what was true. These cases cause great anxiety at the time and occasionally lead to a permanent breakdown. Many, however, by careful management may be tided over the climacteric period of puberty and then all may go well. It is important, however, to be on the guard against any suicidal impulse, and to note its slightest indication as the tendency in such cases is to melancholia and in some instances temptation to self-inflicted injury. Care should be also taken to be quite sure that there is no sexual deviation, and if there be, to treat it, not as moral wrong, which would lead to further mental disquietude and peril, but as a physical evil which, for the good of the body, it is important should be corrected. These deviations are readily recognised by the aggregation of a group of symptoms which rarely leads one astray. They are supra-orbital headache, dilated pupils, a brown umber areola surrounding the eyes, an averted look and a statuesque bearing. This last symptom alone is often very conclusive and may be regarded as certain if associated with the preceding; occasionally the statuesqueness is so marked as to resemble a minor cataleptic state.

Moral insanity is met with in childhood and youth. It has fallen to my lot to have had a great many illustrations brought under my notice—cases of purposeless theft, purposeless lying, and purposeless mischief. They are difficult cases to treat, and make great demands on one's resources. The subjects of this condition are sometimes intellectually bright, and have an amount of address which makes them extremely troublesome to their friends and those who have to guide them. I was consulted some years since about a boy who displayed such destructive energies on toys and every household appliance that he could get into his possession, that his friends thought it indicated a latent mechacal talent, as he had also manifested mathematical ability he was apprenticed to a firm of engineers. Here his pleasure in creating astonishment led him to introduce sand into the mechanism of the machinery he had to overlook, apparently getting amusement out of the consternation and inquiry which his evils deeds induced. He managed for some time to conceal his delinquency by clever lies; but at length the delinquency was fastened on him from his having allowed a traversing machine to go beyond its support in order that he might see the mischief that would ensue. He had good musical talent, and acquiring some skill as an organ player, he would play occasionally in the church, and suddenly stop to enjoy the discomfiture his irregularity produced. Eventually he became a thief and was several times in danger of being brought under the criminal law. All his delinquencies were conceived and carried out with great skill; there was no intellectual lesion, but his moral and affective faculties were thoroughly dormant. He saw no wrong in what he did, and he entertained no affection for his parents, who were in a state of perpetual agony. Had he been a member of a lower stratum of society he would have become a jail-bird. Great pains were taken to prevent his getting into the hands of the police, and, the period of puberty passed, he has reached manhood with improved moral sense, and is now getting his living by his musical talent in a respectable and honourable way.

(a) Delivered before the Medical Society of London, Monday, Jan. 31st, 1887.

More frequently moral insanity is associated in children and youths with some amount of mental backwardness. The backwardness may be very slight, but yet sufficient to prevent their taking appropriate place in form or in the playground. The manifestations of moral insanity in such cases are multiform. I have seen a boy who had brought from school sixteen watches without being discovered by the sufferers or the principal of the school, and this so cleverly as for a long time to elude detection.

A still more dangerous form is a tendency sometimes met with of setting fire to articles of furniture, often where it would be perilous to themselves as well as others.

This is a convenient place to treat of the interesting class of cases for which the term "idiot savants" has been given, and of which a considerable number have come under my observation. This name has been applied to children who, while feeble-minded, exhibit special faculties which are capable of being cultivated to a very great extent.

Extraordinary memory is often met with associated with very great defect of reasoning power. A boy came under my observation who, having once read a book, could ever more remember it. He would recite all the answers in "Magnall's Questions" without an error, giving in detail the numbers in the astronomical division with the greatest accuracy. I discovered, however, that it was simply a process of verbal adhesion. I once gave him Gibbon's "Rise and Fall of the Roman Empire" to read. This he did, and on reading the third page he skipped a line, found out his mistake and retraced his steps; ever after, when reciting from memory the stately periods of Gibbon, he would, on coming to the third page, skip the line and go back and correct the error with as much regularity as if it had been part of the regular text. Later on his memory for recent reading became less tenacious, but his recollection of his earlier readings never failed him.

The faculty of number is usually slightly developed with feeble-minded children while memory is fairly well developed, and yet I have had under my observation cases where the power of mental arithmetic existed to an astonishing extent. One boy, about twelve years of age, could multiply any three figures by three figures with perfect accuracy, and as quickly as I could write the six figures on paper, and yet, so low mentally, was he, that although having been for two and a half years in almost the daily habit of seeing and talking to me, could not tell my name.

Memory of tune is a very common faculty among the feeble-minded; they readily acquire simple airs, and rarely forget them. I have had one boy under my observation who, if he went to an opera, would carry away a recollection of all the airs, and would hum or sing them correctly. In none of the cases of "idiot savant" have I been able to trace any history of a like faculty in the parents or in the brothers and sisters, nor have I had any opportunity of making an autopsy, except in one instance. This was in the case of a boy who had a very unusual faculty, of which I have never since met another example, viz., the perfect appreciation of past or passing time, He was seventeen years of age, and although not understanding, so far as I could gather, the use of a clock face, could tell the time to a minute at any part of the day, and in any situation. I tried him on numberless occasions, and he always answered with an amount of precision truly remarkable. Gradually his response became less ready, and he would not or could not reply unless he was a little excited. He had to be shaken like an old watch, and then the time would be truely given. Gradually his health became enfeebled and the faculty departed. At the autopsy I found that there was no difference in the cerebrum from an ordinary brain, except that he had two well-marked and distinct soft commissures. My explanation of the phenomenon was that as every movement in the house was absolutely punctual he had data from which he could estimate the time by accurate appreciation of its flux. All these cases of "idiots savants" were males; I have never met with a female.

It happens to the congenitally feeble-minded as to the strong-minded to have deviations from their normal standard. There is therefore every form of mental aberration to be met with among them. They become the subjects of acute and chronic mania, of acute and chronic melancholia, and of dementia. It is curious to witness the change which may take place in the mental and moral condition of one deprived to a great extent of intellectual power. Feeble-minded children are not naturally suicidal; they are liable to meet with accidents from their not having any sense of fear, or from not being able to work out the logical sequence of any act, but, under the influence of a melancholic state, they do sometimes become suicidal. Occasionally, under the influence of acute mania, the feeble intellect of the youth becomes fanned into a brighter flame, and he may say things which are quite in advance of his ordinary powers, becoming for the time quick in repartee or pertly rude. The taciturn may become loquacious, the timid and respectful proud and defiant, and the amiable and tractable abusive and destructive. Occasionally too, a remarkable change takes place in those who are temporarily the subject of the delirium of fever. Three remarkable instances have occurred to me of boys who had never been heard to speak, making use of well-formed sentences during the high febrile state of acute pneumonia in two instances, and of scarlatina in another. In the case of one, who was the subject of pneumonia, the other boys who were in the Infirmary at the time were frightened by the febrile ejaculation of their usually speechless companion.

There are two ailments from which, according to my experience, the congenitally feeble-minded are remarkably free, viz., chorea and hysteria. I cannot call to mind, among the large number of cases that have come under my notice, a single case of acute chorea. I have met with cases of chronic and persistent unco-ordinated movements but not with the acute cases so common in a general hospital or in a hospital for children. I have assumed that it is partly owing to the lessened emotional life of my patients. The same reason may account for the rare occurrence of hysteria. This defective emotional element in the feeble-minded spares them much grief. Although very affectionate, they will hear of the loss of beloved relations or friends without emotional disturbance and with a remarkable philosophy. They live very much in the present, and are not perturbed by the troubles of the past or the unexperienced future.

Epilepsy is a very common complication of feeble-mindedness. Of the whole number that have come under my observation, 24 per eent. have been at some period of their lives epileptic. This appears to be a very large average and indicates to what a great extent the treatment of idiocy is the treatment of epilepsy.

Epilepsy often appears for the first time at puberty and subsequently ceases. Occasionally the status epilepticus supervenes with the worst possible results.

Catalepsy is met with among the feeble-minded, but always in my experience associated with impure habits.

The physical deviations of the feeble-minded are very important. I have already referred to the lessened common sensation and defective co-ordination to which they are prone, to their diminished sense of taste and smell, and to their sight. Hearing is often obtuse, and is, as I have said, frequently a cause of deferred speech. They are very prone to eczematous eruptions in the flexures of the joints and behind the ears. The skin gives evidence of the degeneration in its tendency to unnatural unions; just as the petals of a corollifloral exogen indicate a lower grade than the distinct petals of a thalamifloral so do webbing of the fingers and toes and adhesions of the lobules of the ear suggest marked inferiority. Dr. Laycock many years ago called attention to the prevalence of ear abnormalities in people of a degenerate type, and my own observations coincide with his. Lobules absent, lobules adherent, helices defective, and the entire pinnæ misshapen or shrunken, are very common among the congenital feeble-minded. The implanttation of the ear is often too far back, giving an exaggerated facial development. I have had under my observation very remarkable examples of webbing, both of toes and fingers, in all cases associated with adherent lobules of the ears.

The prevalence of phthisis as a cause of death among the feeble-minded varies very much with the nature of the soil on which they reside. Through the admirable researches of Dr. G. Buchanan we now know how much associated a damp clay soil is with the existence of phthisis. He has taught us that measures which have been taken in some towns and cities for their drainage in consequence of the prevalence of zymotic disease, have resulted in diminishing the mortality from pulmonary consumption in a remarkable degree.

Nothing is more remarkable than the readiness with which feeble-minded children succumb to acute disease of any form, or the way in which they are injuriously affected by climatic changes. The incidence of illness should be narrowly looked for and promptly treated; the thermometer is of great value in indicating the need of early precautionary measures. Before the introduction of the clinical thermometer the principal indication of deviations from health was loss of appetite. I have known a boy in whose case the first suggestion of illness consisted of a face suffused with tears, because, as he said, the boy who had sat next him at tea had eaten three slices of bread and butter and he could not eat any. This was the prelude to one of the most serious ailments to which they are subject, namely, bronchopneumonia.

The diagnosis of idiocy is of importance, both in order that the child may early be put under proper training and for medico-legal purposes. The profound cases are not difficult to diagnose, especially if associated with microcephalism or with marked asymmetry of cranium. The congenital class is that which has to be considered in early life. There is a marked want of muscular power, as indicated by the inability to support the head and to use the hands for prehension. The eyes look out as if on an objectless world, and the attention is not arrested by the usual expedients to excite recognition in infants. To the most loving endearments there is no responsive smile, and the infantile cooing is replaced by a wailing cry. Still later the power of standing is deferred, and walking is an accomplishment which may never be attained.

I have already referred to the physical deviations in congenital idiots, such as the deformed cranium, the vaulted palate, and ill-developed ears, and these come to our aid in a remarkable way in the question of diagnosis. The same may be said of the ethnic characteristics, especially the Mongolian type, which is so significant of congenital mental incapacity. In the developmental class I have already referred to the prow-shaped frontal bone as being highly typical and an aid to diagnosis, certainly helping us to assign a case to this division where there are psychological grounds for apprehending mental deficiency. With regard to the accidental class, physical deviations do not come to our aid. They have usually none of the grave deviations of conformation which we meet with in the congenital class. They have, as I have said, nothing in their look which would indicate their mental decadence. On the contrary, they in most cases during their childhood present physical features but little indicative of the terrible disaster which has befallen them; except in the paralysed sub-class they are fleet and mobile, and mischievous to a degree. They are irritated by constraint, are intolerant of having their heads examined, and try to escape from one's ken, they pull open every drawer that it unlocked, shake the handle of the room door to procure its opening, and sweep with their hand the ornaments off one's table that they may enjoy the rattle. They alternate their mischievous pranks with shrill and unmeaning cries. They rarely speak, are fond of feeling things with their tongue, and run about to get some fresh object on which to indulge this freak. They too frequently return a proffered kiss by a bite, and fill up the intervals of their noble mischievousness by blowing bubbles with saliva on their lips. They have this important diagnostic feature, that they live entirely in a world of their own; they do not listen with a childlike curiosity to the conversation which is going on in their presence—a conversation which is all-important to them, and in the outcome of which they are the most interested parties. They hear what is said, but they do not attend, nor can their attention be arrested, except by diverting them into new channels by a more attractive trial. They have usually great intensity of purpose, and succeed in having their own way, the mothers giving up the contest for the sake of peace. Slavering is a very common sign among the members of the three classes, arising sometimes from inattention, or from hyperæmic condition of the salivary glands, from prognathous form of jaw and inadequate size, or want of muscular power of lip, from inco-ordinate movements of the tongue, and sometimes from a combination of two or more of these conditions. Automatic movements are also very common; these may consist of rotatory movements of the head on its axis, of the body from side to side, or from back to front, or rhythmical movements of the fingers before the eyes.

There are a large number of boys and girls who are dull and backward and who develop tardily, but do arrive at last at a fair amount of intellectual power. They are the *enfants arriérés* of the French writers. It is very important that their condition should be differentiated from that of idiots. Their state gives rise to much solicitude, and the prognosis depends very much on a right appreciation of their condition, as they respond very much to proper training. The test which I have found most useful is one suggested in the first instance by Dr. Charles West. In any given case we have to ask ourselves,—Can we in imagination put back the age two or more years and arrive thus at a time perfectly consistent with the mental condition of our patient? If he be a backward child we shall have no difficulty in saying what period of life would be in harmony with his state. If, however, he be an idiot there is no amount of imaginary antedated age to which the present condition of the child corresponds.

I have already referred to the frequency with which lesions of speech occur among the feeble-minded. They often constitute a basis of great interest and importance for a diagnosis. The absence of speech when a child arrives at five or six years of age is in itself a matter for grave anxiety. It will be usually possible to refer the condition to one of three causes: (1) The child is completely deaf or has some slight congenital defect of hearing; or (2) there is some defect of conformation in the tongue, palate, or lips, which prevents language being acquired; or (3) the child is defective in mental power, and either does not require speech from the absence of ideas or has an inability to convert ideas into words. When the child is being trained the parents regard the acquisition of, or improvement in, speech as the touchstone of progress, disregarding a number of other faculties which have been developed, or evil propensities which have been effaced. In many cases they are right, the absence of speech without deafness or deformity being a very important indication of a grave mental lesion.

A fertile field for the investigation of the morbid anatomy of idiocy is opened up by the inquiries of Hitzig, Jackson, and Ferrier into the localisation of function, and by improved microscopy aided by the use of staining agents. A very prominent characteristic is the diminished weight of the encephalon. Sometimes the diminution is very great, as in the microcephalic or Aztec variety. I have had the opportunity of examining several, but the most complete example was the brother of the boy described by Professor Marshall in the "Transactions" of the Royal Society.

Cases of extreme asymmetrically developed brains are not infrequent; a very characteristic example I published in vol. xx of the "Pathological Transactions," and many similar ones have come under my observation. The most frequent want of development is that of the occipital lobe. Where there is any approach to smallness of the brain this lobe is the part which shows greatest want of development.

Hypertrophy of the brain is not infrequently met with In one very remarkable case that came under my observation there was the co-existence of a huge cranium with all the sutures completely ossified. So thoroughly was this the case that if it had occurred with a microcephalic cranium it would have been a strong argument in favour of the causal influence of premature synostosis in microcephalism.

Absence, more or less complete, of the commissures is met with. In 2 per cent. of the cases I have examined there has been almost entire absence of the corpus callosum, and in 8 per cent. absence of the soft commissure.

Pallor of the grey portion of the encephalon is very frequently met with in the brains of feeble-minded children. Looking back over my post-mortem notes, nothing is more striking than the frequency with which extreme pallor is mentioned. I cannot but think that this affords indications for treatment as well as a basis for hopefulness in the possible functional improvement of the cerebrum.

(To be continued.)

NOTES FROM THE

HISTORY OF MEDICINE AND OF MEDICAL OPINION

FROM THE EARLIEST TIMES.

By Surgeon-General C. A. GORDON, M.D., C.B.,
Hon. Physician to H.M. the Queen.

(Continued from p. 72.)

In the early part of the eighteenth century, Boerhaave endeavoured to collect all that was valuable from the writings of preceding authors, and by means of such materials to form a new system. The system so formed combined the humoral doctrines of Hoffmann and the mechanical of Bellini (Bostock, p. 193). His defects that he took on trust opinions instead of results of observations; also that in his theory of the solids of the living body he viewed them rather as inanimate bodies than as endued with life.

Haller, as a reward of long and well-directed experimental research, "established his theory of irritability and sensibility as specific properties," attached respectively to the muscular and to the nervous systems (*id.*, p. 198). That doctrine was opposed by many individuals of high respectability, and affirmed by others, the controversy being carried on with great acrimony.

Out of the divisions thus created arose the sect of Semi-animists, led by Wyatt, whose tenets later improvements in physiology and chemistry showed to have required modification (*id.*, p. 204). According to the theory so-named the "sentient principle" is a principle necessarily belonging to the living body, and imparting to it its vitality, although distinct in its nature from any of the properties of a mere mechanical agent (p. 201).

According to Cullen, the different organs of the body are severally possessed with specific and appropriate powers, distinct from those attached to inanimate matter. This regulating principle, the *vis medicatrix naturæ*, has a tendency to preserve the body in health, to control the cause of disease, and to restore the body to health. It is not superadded to the body like the archæus and the anima, but is one of the powers or properties necessary to the constitution of the living system. In place of all explanations founded upon mechanical or chemical reasoning "the vital action" of parts was substituted, and more especially that of the capillary arteries (p. 208). The system of Cullen, founded on the above data, was one of "rational empiricism," and for a time it, to some extent, superseded the taste for rude speculation and hypothesis (p. 209). He, however, by no means ignored inductive reasoning and investigation; some of his own speculations also exhibited more ingenuity than judgment.

Opposed to the hypothesis of Cullen was that of Brown. According to the latter, medicine, heretofore a conjectural art, was to be built upon "a few certain and fixed principles," very similar indeed to doctrines enunciated in times more recent by certain medical "scientists," who, like Brown, announce their system with confidence unwarranted by fuller information. Of that system, also, as of its present representatives, we learn that it at first obtained many adherents, principally among the students and younger members of the profession (Alison's "Hist. of Med.," p. lxiv). The human body possessed a specific property called excitability. If any cause rendered this property excessive, exhaustion or direct debility was the result; when defective, it caused indirect debility. Diseases were in consequence classified as sthenic and asthenic, according as they were conceived to depend on these states of direct or indirect debility (Bostock, p. 212), treatment being directed solely with reference to these conditions without regard to specific symptoms. The insufficiency, and erroneous tendency of the doctrines of Brown were detected by fatal experience, and (in Italy) "the delusion was removed" (p. 221).

Another theory of this date was that of "homœopathy," which included that of "potentiality," or "dynamitisation" of drugs. According also to it, disease was a something to be "removed," instead of a "condition" to "change." The expression "to expel" disease, made use of by its advocates, indicates a very remarkable correspondence between their tenets and those of some advanced scientists of the present day.

In the latter half of that century a theory of medicine which united certain parts of the doctrines of the Mathematicians, the Humoralists, and the Vitalists was formulated by Lieutaud, who was himself an eclectic (p. 217). On the continent the prevailing hypothesis united those of the Humoralists, the new views regarding the actions of the nervous system, and the contractility of the muscular fibre (p. 218). At this date De Haën, a man of great learning, united with much practical skill, and a talent for correct observation, was a zealous opponent of Haller's theory, and no less decided in his opposition to the practice of inoculation, and the use of various new remedies then for the first time introduced into practice; an opposition on his part which led to his being characterised as "unreasonably prejudiced against new opinions, and even new improvements in his art." In Italy, anatomical pathology took its rise during the previous century (p. 219). In that country, towards the close of the eighteenth century, Bursorius expressed his doctrines; they embraced those of the Humoralists, Solidists, and the Vitalists (p. 220).

During that century descriptions were given of "new diseases," or of those "which had not been discriminated with sufficient accuracy from others that in many respects resembled them." Attention was also paid to epidemic, endemic, and contagious disorders, and to local and climatic conditions as affecting them. Consideration was shown to accounts of diseases incidental to the army and navy, and medical literature much enriched by contributions from those services (p. 222). Practitioners were satisfied with recognising the value of particular drugs in certain diseases, without endeavouring to discover the nature of the occult qualities on which their operation depends (p. 225). Mead wrote on the "nervous liquor," which he supposed to be "a quantity of universal elastic matter diffused through the universe," *i.e.*, "the luminous ether" of Newton (Encyc. Brit.). In this system were explained the several phenomena of health, and of disease; health as "the maintenance of proper tone" of the body; some diseases as excess of tone or "spasm," others by "atony" or want of it. Clinical teaching was introduced for the first time as a part of medical education; the teachings of physiology and anatomy were applied to the practice of medicine. To this century also is due the introduction of vaccination as a preventitive against small-pox.

It was in the eighteenth century that Mesmer flourished, and that the medical faculty stigmatised him as a charlatan. He imagined that the stars exerted an influence on beings living on earth. This supposed influence he identified, first with electricity, and then with magnetism; he supposed that it penetrated the universe, and that it affected the nervous system. In 1776, he discarded the use of magnets which he had previously used in the treatment of disease, he having then been led to believe by Gassner that some kind of force resided in himself by which he could influence others; also that this force permeated the universe, and more especially affected the nervous system of men. In 1778 he threw Paris into a state of excitement by the marvellous effects of mesmerism, or, as he called the power, animal magnetism (Encyc. Brit.). [Nor is the circumstance a little remarkable that now, late in the nineteenth century the use of the magnet as a means of "transferring" particular diseases from one person to another finds advocates in the same capital.]

With reference to the general condition of medicine during the eighteenth century, a recent writer has expressed himself to the following effect:—Theories were the curse of the time, men lay their foundation in their own fancies, and then suiting the phenomena of diseases and the cure of them to those fancies. Errors, prejudices, theories actively mischievous prevailed; the mania of hypothesis was at its height. Diseases were classified so as to fit into some hypothesis, or their distribution made to suit the bent of the author rather than the real nature of the disorder (Lock and Sydenham, pp. 40-41).

Dr. Bostock has observed that medicine differs from every other branch of science in that our actual information regarding it does not increase, in any degree, in proportion to our experience; the augmentation of materials rather retards than promotes its progress. In medicine there are certain peculiarities necessarily connected with the subject which render it extremely difficult to appreciate the value of experiment and observation. In modern times, and more remarkably in Great Britain, no one thinks of proposing a new mode of practice without supporting it by the results of practical experience. A method of treatment recommended at one period is, in the course of years, supplanted by another, which in its turn passes "through the same career of expectation, success, and disappointment." As an example in point, he observes that in the course of forty years the treatment of "typhous" fever went through three revolutions of opinion. According to the first it was called a disease of debility, and treated with large doses of cinchona bark and wine; to that method succeeded cold effusion; and it in turn was supplemented by the lancet. At the present time the method adopted is called "the expectant," whatever that may actually mean. He notices the rise of the Homœopathic doctrine, and that of animal magnetism; and with reference to both makes the remark that "no medical testimony is sufficient to establish a fact which is in itself incredible."

He observes that in the eighteenth century little value was placed upon theory as compared with observation, and the collection of facts; at the same time he admits the latter system may be carried too far. The German physiologists (in 1835) afforded a singular admixture of profound investigation and fanciful mysticism. France (at the same date) exhibited an unrivalled assemblage of medical philosophers, both in regard to pathology and physiology. From their united labours most important results were anticipated, but "so far as the practice of medicine is concerned, the benefit is rather in anticipation than in existence." With a few exceptions, French practice is less effective than that of our own country; their "médecine expectante," if less dangerous in the hands of ignorance or presumption, is less beneficial when under the direction of skill and judgment. France is pre eminent for its pathology, Germany for its physiology and anatomy; yet in Germany, as in France, the effect of this scientific co operation on the practice of medicine "is not yet fully experienced." With regard to medical periodicals of the period referred to, "It is very much to be regretted that in too many instances they should be used as a medium of personal animosity, rather than for the promotion of the welfare of mankind" (pp. 226 *et seq.*).

Of the nineteenth century, we read that—Hypotheses were used as means of research, rather than as ultimate conclusions. Physiology and anatomy supplied a basis for all diseases. Before the first half had passed, the study of mesmerism was resuscitated in England, but under the name of hypnotism. The influence so-called, ignored as it had been when first proclaimed, was now considered to have a bearing upon the theory of reflex nervous action, and to explain the phenomena of "inhibitory nervous action." Allied to mesmerism, metallotherapy and massage came into prominence; homœopathy advanced as it had never done before; hydropathy and hydropathic institutions extended throughout the United Kingdom; chloral and anæsthetics were introduced as therapeutic agents, and what was termed a "scientific method" introduced into the investigation and treatment of ills that flesh is heir to. A large number of fevers and other diseases were attributed to "irritation" or inflammation of the intestinal canal; a theory which, soon after its enunciation, was described as "wild" and exploded, but which, nevertheless, reappeared and still continues, more especially in regard to that form of fever called "enteric." The systematic examination of urine, and discovery of the nature of Bright's disease, as also the introduction of auscultation, belongs to the present period. The "zymotic" theory of various so-called "preventible" diseases is also of it, so are the modern views in regard to "specific" poisons, antiseptics, microbes, &c. But diseases continued to occur in isolated cases, and as epidemics, as they have ever done; "one generation of humanity after another passes away, to be in turn succeeded by races of people no less fleeting."

Physic has been described as one of those departments in which there is frequent necessity for the exercise of "an incommunicable faculty of judgment, and a sagacity which may be called transcendental, as extending beyond the simple combination of all that can be taught by precept (Lock and Sydenham, p. 22). Our art (of healing) is not to be better learned than by its exercise and use; and it is likely to prove true that those who have directed their eyes and their mind the most accurately and diligently to the natural phenomena of diseases, will excel in applying the true indications of cure (p. 38). The discovering and assigning of remote causes, which now-a-days engages the minds and feeds the vanity of envious inquirers, is an impossible attempt (p. 42). It is this doctrine of conjunct causes, this necessity for watching the action of compound and often opposing forces, and the having to do all this, not in a machine of which, if you see one, you have seen all, but where each organism has often so much that is different from, as well as is common with all others. Here you must mend your watch while it is going (p. 43). Medicine is not like practical geometry, or the doctrine of projectiles, an application of an abstract, demonstrable, science, in which a certain result may be infallibly drawn from certain data, or in which the disturbing forces may be calculated with scientific exactness (p. 457). In all disease there is an inscrutable specific property which eludes the keenest anatomy (p. 52). We are now-a-days in danger of neglecting our art in mastering our science, though medicine in its ultimate result must always be more of an art than a science. This distinction between the science and the art has often been called the *cunning* of medicine. Inasmuch as human nature cannot contain more than its fill, a man may not only have in his head much scientific truth which is useless, but it may shut out and hinder, and render altogether ineffectual the practical faculties for whose use his knowledge was primarily got. All professional men labour under the great disadvantage in not being allowed to be ignorant of what is useless (p. 58). The real physician is the one who cures; the observation which does not teach the art of healing, is not that of a physician, it is that of a naturalist (p. 94).

(*To be continued.*)

We are requested by the Hon. Treasurers of the "Jacob Testimonial" to state that the additional subscriptions received by them during the past week will be found duly acknowledged in our advertising columns.

PREVENTIVE MEDICINE AND ABORTIVE TREATMENT.

By C. R. ILLINGWORTH, M.D. Ed., M.R.C.S. Eng.,
Medical Officer for the Rishton District, Blackburn.

(Continued from page 569, last vol.)

After treating seventy cases of measles in the epidemic I have referred to, I began to think that the acetate of ammonia might have some action in producing an over-fluid condition of the blood. I accordingly gave the nitrate of potash in from three to four grain doses with the biniodide of mercury mixture, until the third day of the rash, and then the iron as before. I found the refrigerant action of this salt most valuable. It certainly also left patients in a better condition after the subsidence of the rash. There was less pallor and less debility. My suspicions of the acetate of ammonia were thus, to my mind, confirmed. Like the carbonate, though not to the same extent, it not only acts upon effused fibrin, but to a certain extent damages the fibrin-forming power of the blood, and the hæmoglobin of the corpuscles. Potash salts (and particularly the nitrate) seem to have the valuable property of reducing febrile conditions without acting thus deleteriously upon the blood. (Jones's and Sieveking's observations thus appear to receive confirmation, *vide* p. 21 "Deficiency of Fibrine.")

And now for a description of a further step I have taken in the treatment of this complaint. The great tendency in measles, to the production of over-liquidity of the blood, from the proximity (no doubt), of the infecting material, to the circulation in the lungs; the fact that, unlike those of scarlet fever, the germs of measles have their vitality exhausted in three days from the first appearance of the rash upon the face, and act upon the skin only; and finally, the perfect compatibility of the nitrate of potash with the perchloride of iron, induced me to prescribe this mixture of liquefacient and hæmatinic medicines from the very commencement of the rash, with the object of combating the dangerous defibrinating tendency of the disease at as early a period as possible.

At the end of the sixth day of the disease, or the beginning of the seventh, as before, I prescribed steel only, for by that time, all the concurrent febrile symptoms have subsided. The happiest results marked this change of treatment. The tongue rapidly became moist and clean; the children more quickly regained their liveliness of manner; there was less secondary bronchitis; and the resulting spanæmia was so much less marked that the complexion was almost unaffected.

I have therefore the utmost confidence in recommending this method of treatment for measles, from the first. I prescribe as follows for a child of from two to four years of age:—℞ Liquor ferri perchloridi fort. ♏vi—xv.; potass. nitrat. ʒjs—ʒj; syrupi ℥ss.; aquam ad ℥iss. One teaspoonful every two hours, day and night. For an adult I double or treble these doses, according to age. If the liquor ammoniæ acetatis be prescribed on account of its superior diaphoretic properties, I would suggest that it be not given after the fourth day of the disease, *i.e.*, the first day of the rash.

Out of one hundred and seventy cases attended during the last ten weeks there have been ten deaths, viz, two from suppressed measles invery young infants, two from croup during the acute stages of measles, two from secondary croup; two from secondary bronchitis, and two from secondary meningeal effusion. All these deaths occurred between the fiftieth and hundredth cases. There were no fatal cases after the commencement of the combined liquefacient and hæmatinic treatment, with steel and nitrate of potash. In regard to croup, besides the astringent and hæmatinic remedies I have advocated, with counter-irritation, I would suggest the application of a solution of nitrate of silver (30 grains to the ounce) by means of a laryngeul brush, to the interior and vicinity of the larynx at the first onset of the attack. In five out of six cases which recovered from concurrent and secondary croup, the astringent hæmatinic and counter-irritant treatment was sufficient to effect a cure; in the sixth, a case of secondary croup, I used the nitrate of silver with good results.

The difference in effect upon the fibrin-forming power of the blood, between the ammonia and soda salts on the one hand, and the potash salts on the other, is worthy of further notice. It is usual, for instance, to prescribe ammonia and the acetate of ammonia in bronchitis, pneumonia, and broncho-pneumonia. These medicines are very valuable ones, but there is danger in continuing the use of them too long in acute chest disease, a risk, viz., of inducing a condition of over-fluidity of the blood, with fatal capillary bronchitis as a consequence. I have no hesitation in affirming that I have saved life in capillary bronchitis and broncho-pneumonia by from one to five minim doses of the strong perchloride of iron (according to age) given every hour or half-hour. The indications of an over-fluid condition of the blood in these cases are the dusky complexion, rapid rattling breathing, and livid lips of the patient, whose blood, from imperfect aëration due to abundant secretion, is rapidly losing its fibrin-forming power, and filling the air-cells with its fluid elements. In every case of bronchitis, as soon as the tongue is moist and clean, I give steel in large doses (generally with gentian and chloric ether), and I am of opinion that the combination of steel and nitrate of potash is capable of extended usefulness in many acute chest affections and febrile conditions.

Foreign Department.

ELECTROLYTC CAUTERISATION FOR THE TREATMENT OF LUPUS VULGARIS.

By Dr. G. GÄRTNER and Dr. S. LUSTGARTEN.

Having taken in hand a number of lupus patients in the Kaposi Klinikin Vienna, the authors report very favourably on the results obtained. They used a current from a strong battery (twenty-four Leclanché or chromic acid elements) whose elements were set into action altogether. The positive pole was represented by means of a sponge electrode, which was fastened in the form of a Gärtner's movable electrode on to the forearm of the patient. From the zinc pole the current passed through Gärtner's graphite reheostat, and an oaken compass for absolute measure (either Edelmann's galvanometer or Kohlraush's current index) to the cautery electrode, one of the planes after being slightly bent, a fine silver plate two cm. in diameter was let into a hard Indiarubber ring, which likewise with the help of the movable electrode was pressed upon the sore place on the skin.

The authors recommend before the attempt to smear the surface of the part to be operated upon with soap liniment or some other kind of soap not too fatty. If the electrodes are in the desired connection there will be produced by means of the rheostat a gentle and regular current rising from 5 to 8 milliampères, whereby the patient only perceives a slight burning. The further action of the current, lasting about ten minutes, is quite or almost painless. After the expiration of this time the cauterised parts are excoriated, sodden, and in a few minutes a tenacious strongly alkaline matter trickles out. Then follow iodoform dressing, and for the most part aseptic healing under the scab. As the authors themselves assert cauterisation cannot be used everywhere. If the lupus is very deeply seated electricity must not be used; but if the infiltrated lupus is immediately under the surface of the skin, or if ulcers already exist electricity can be used in almost all parts.

With regard to papillary forms (from which the verrucose forms are again excluded) the whole mass of epidermis must be got rid of by means of maceration and washing with soap; in ulcerated lupus where the cauterisation is not quite so painless, the wound must be painted several times with a five per cent. solution of cocaine. The authors point out as the advantage of their method over other treatments, along with the almost complete absence of pain, that by the peculiar treatment only the diseased parts are cauterised, and the healthy tissue is left untouched. Whether the method will be brought into common use is very questionable, because the large apparatus is rather complicated and expensive, and too much time is required. Further, it is not applicable for lupus on many parts of the body, *e.g.*, isolated parts of the face, nose, ear, &c. It can, however, be recommended where the lupus is localised upon the trunk or extremities. There are two important points in the very interesting communication. In the first place the electrolytic cauterisation in a physical sense has nothing to do with electrolysis. A current of one ampère intensity decomposes in one second about 0·1 mgrm. $H_2 O$; here the applied current at most 0·01 ampère, decomposes in ten minutes about 0·6 mgrm. $H_2 O$, or an equivalent mass of tissue, an accomplishment which for the real tissue destruction taking place—a result produced by the alkali *in statu nascenti*—cannot be taken into consideration. Further, the demand now made, as far as we know for the first time by Gärtner and Lustgartner, is very important, that in every kind of electrolysis an absolute galvanometer shall be made use of, because the number of elements present does not yield any measure for the strength of the current, and only under the exact control of such a galvanometer, can any definite effect be brought about.

Clinical Records.

CASES FROM HOSPITAL AND PRIVATE PRACTICE.(a)

By J. Appleyard, M.B., F.R.C.S.,

Surgeon to the Bradford Infirmary.

The following cases—at least those of malignant disease—were brought before the Society as aids to prove or disprove the local or general origin of cancer. The short time allowed for a paper, necessitated brevity in description as well as in the analysis of each individual case.

Case I. *Epithelioma of Lower Lip.*

A man, æt. 71, with the history of a horny growth on the left half of the mucous border of the lower lip, twelve years ago, followed by a slight scabby condition of the site of the horn, without any evident papillation, which persisted till the day of his death, with little or no local change in the lip itself. The lymphatic glands, however, about the angle of the jaw, and in submaxillary regions, became enormously enlarged, causing difficulty in moving neck and in swallowing, and leading to death by exhaustion in December, 1885, about twelve years after the initial lesion in the lip was recognised. No operation was performed, so that the case is interesting for its long duration, the very slight and very slow change of the initial lesion in the lip and the enormous secondary growth in the lymphatic glands. Suppose the initial local manifestation had been excised eleven or twelve years ago, thoroughly and freely, what influence would it have had on the future history of the case?

Case II. *Scirrhus of Mamma.*

A female, æt. 61, whose left breast was removed in July, 1879, for a scirrhous mass the size of a hen's egg. The patient's health continued fairly good until July, 1886, when loss of appetite and shortly afterwards loss of flesh came on, and on October 10th, 1886, the liver was found greatly enlarged, and on its surface two hard firm tender plates which were diagnosed as secondary scirrhous deposits in the liver. Ascites, and œdema of the legs rapidly came on and the patient died November 28th, 1886, about seven and a quarter years after the excision of the breast. Up to the last the scar and the axillary and supra-clavicular glands were free from any enlargement or appearance of disease.

Query.—What would have been the effect on the progress of the case if the mamma had been excised at an earlier stage, before the mass had attained anything like the size of a hen's egg.

Case III. *Recurrent Scirrhus of Mamma.*

A woman, æt. 56, whose left mamma was excised a second time in August, 1885, for recurrent scirrhous cancer, the first operation having been performed ten years previously. She was discharged with the wound perfectly healed, Sept. 11, 1885. How the case has progressed since her discharge, I am not able to report, but she has never returned to show herself, and a letter addressed to her has *not* been returned as a dead letter.

Case IV. *Epithelioma of Glans Penis.*

A man, æt. 48, with a tight prepuce from infancy, and no family history of cancer, &c. When seen on April 10th, 1883, had a dry, whitish, rough-looking ulcer with indurated raised edges, rather smaller than a shilling, occupying the furrow and part of the right side of the glans penis—the prepuce (inner layer) being slight involved. He stated that two years ago, he felt a hard patch through the skin of the prepuce, with a sharp edge and about the size of a pea. There was no discharge and no pain, except when he knocked his penis against anything. He was treated by a quack, apparently for a hard chancre, but no improvement resulted. He saw a medical man who told him, he had a wart, and applied some caustic, which turned it white—a slough separated—but still it grew, and began to sprout more vigorously. Dr. Goyder then saw the case and kindly sent him to me, and we were agreed that the case was one of epithelioma, requiring prompt measures. The penis was amputated through the middle on May 14th, 1883, and the wound healed nicely. In November, 1883, a small nodule developed on dorsum of penis, half an inch from the meatus, which was excised, and no further recurrence has taken place. The patient is quite well, with the exception of a stricture at the meatus. A section under the microscope, shows nests of epithelial cells, so characteristic of epithelioma (a section shown). Three years and eight months have now passed since the operation, and the patient is quite well.

Case V. *Epithelioma of Glans Penis.* (*Specimen shown.*)

A man, æt. 58, without any family history of cancer, had an ulcer about the size of a shilling with a warty outgrowth, involving the right side of glans and of prepuce. No previous phymosis. Dr. Denby, who asked me to see the case with him, agreed that the case was one of epithelioma, and the penis was amputated one inch behind the glans, December 29th, 1885. There has been no recurrence, but a stricture of meatus to some degree complicates the case.

Case VI. *Epithelioma of Glans Penis.* (*Specimen shown.*)

A man, æt. 69, with no family history of cancer, and no phymosis, was first seen Aug. 23, 1886, by the House-Surgeon, Mr. J. A. Kempe, when there was a hard lump the size of a half-marble projecting from right side of glans penis. It extended back as far as the corona, was vascular, discharging thick pus, and very like a ripe strawberry. Prepuce quite free, although a little swollen opposite the little mass. Lymphatic glands in both groins a little indurated generally, but he says they have been hard as they are now for years. Penis was amputated two inches behind glans on Aug. 27th, 1886, and in order to guard against stricture of the meatus, which resulted in the two previous cases, the spongy or urethral portion was cut half an inch (at least) longer than the corpora cavernosa, the floor of the urethra divided, and the edges of the mucous membrane stitched to the skin all round. There was a little sloughing after the operation, but the wound had healed by 16th September, 1886. The urethra admits No. 12 English catheter, and there is no approach to a stricture.

Case VII. *Swallowing a Steel Shawl-pin.*

A girl, æt. 7, swallowed a steel shawl-pin 2¼ inches in length, with a round black glass knob at the end. There was no symptom of any kind, and nothing could be seen or felt. Solid constipating diet with small doses of mist. cretæ aromat. were prescribed, so as to involve and thus convey the pin safely through the intestines. On the 3rd November the pin was passed imbedded in a solid motion, having been retained ten days. During these ten days she had passed in all five motions, and each one solid.

(a) Read before the Bradford Medico-Chirurgical Society, January, 1887.

Case VIII. *Brass Boot-hook in Larynx.*

A little boy, æt. 5, swallowed a little brass bootlace hook-and-eye on the 17th November, 1886. He was seen three days later (Nov. 20th) by Mr. Kempe, house surgeon at the Infirmary. His parents said that he had vomited every day since the 17th. He had a little hacking cough, a hoarse voice, and said he had pain over the trachea above the sternum, which he localised by his finger. No foreign body to be seen or felt in the throat, but the pharynx and epiglottis redder than natural. Expansion of chest good on both sides, and no physical signs indicative of any interference with entrance of air into trachea or lungs. It was thought advisable, now that three days had passed, to do nothing except put the child to bed and carefully watch and await events. On Nov. 27th the lace-hook was coughed up, having been about ten days in the air passages, probably in the larynx, in the interval between the true and false vocal cords on one side.

◆

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

Friday, January 28th, 1887.

Dr. Broadbent, President, in the Chair.

Dr. Broadbent made his Inaugural Address as President of the Society, and expressed his high sense of the honour and responsibility attaching to the post. If he had had an ambition outside and beyond the performance of his duty, it was certainly that of figuring on the honoured *rôles* of one or other of the societies. Alluding to the progress which had been made in the study of morbid anatomy, pathology, and therapeutics, he congratulated the profession on the fact that every day tended to render practice more scientific, and that pathology and therapeutics now went hand in hand. Diagnosis was one of the most important elements of success in the career of medical men. A well-known barrister of his acquaintance, in his post-prandial chat, was wont to say that, to paraphrase an aphorism of Demosthenes the first element of success at the Bar was good animal spirits, the second, good animal spirits, and the third, good animal spirits. In the same way he would be disposed to say that the great element of success in medicine was diagnosis. By diagnosis, he meant careful and exact localisation of lesions. It was not diagnosis to say that a patient had paraplegia, unless the nature and site of the lesion was ascertained. As to the mere fact of some cases proving exceptional, he recalled the saying of Sir James Paget, that "an exception to one rule was in reality the first indication of another and possibly unknown rule," and might, therefore, be the means of enabling the careful and attentive observer to carry ont useful observation on a new line. He observed that in the Transactions of the society, the surgeons appeared to better advantage than the physicians, a state of things probably attributable to the fact that physicians' cases did not lend themselves to exhibition as did the surgeons' cases. The physician could, and often did, point to the arrest of phthisis in individuals and communities; the progress of Bright's disease might be staved off indefinitely if the patient only carried out the treatment laid down for him; but such cases scarcely admitted of being shown, and in any case did not appeal to the attention in the same way as the more palpable results of the surgeon's intervention. He deprecated anything in the nature of scepticism in regard to the use of drugs, and declared that when physicians used drugs they did so in good faith. Alluding to the class of drugs known as antipyretics, he said that while very useful in a certain category of cases, the mere knowledge that they lowered the temperature was not a sufficient justification for their use. It was necessary for the physician to know *how* the temperature was lowered before he ventured to lower it. The mere existence of fever was not a sufficient reason, and there were many cases in which it was doubtful whether a reduction in temperature was desirable or beneficial to the patient. The physician was not in a position to say that a high temperature was, *per se*, a symptom to be combatted, since it might be a necessary item in the evolution of the morbid phenomena. Referring to the employment of the salicylates in the treatment of acute rheumatism, he acknowledged that many of the inconveniences and sequelæ of that disease were abridged or prevented by its use. At the same time he enjoined a certain caution, especially in prolonged courses of the drug. He said that, since its use had become general, he had certainly seen deaths from rheumatic fever of a kind he had not met with before. In conclusion, he thanked the Society for the honour they had conferred upon him.

Mr. Henry Morris on a case of

CALCULOUS DISEASE OF BOTH LUNGS; WITH REMARKS ON THE SURGICAL TREATMENT OF CALCULOUS KIDNEY GENERALLY.

A woman, æt. 40, was sent to Mr. H. Morris at the Middlesex Hospital on June 15th, 1886, by Mr. Nunn, for the purpose of undergoing an operation for calculous disease of the right kidney, associated with a purulent fistula of long standing in the right loin. The patient was very ill at the time, had passed several small calculi, and complained of severe pain in the right loin, and frequency of micturition. Within a few days some pain had also been felt in the left loin. There was a history of albuminuria of long standing. On June the 18th the right kidney was explored through an incision in the loin. The tissues round the kidney were condensed, indurated, and tenaciously adherent to the renal capsule, the kidney was small and hard. On cutting into the kidney several small calculi and some fragments of pyogenic membrane, but no pus, were removed. The operation was followed by no relief, and more intense pain was experienced on the left side. Partial and then complete suppression of urine followed, and the patient died comatose on June 23rd. At the post-mortem examination the left kidney was found very large and white, and with a great increase of cortical substance. It contained two cysts filled with pus, in one of which there was about two hundred small calculi. Numerous other calculi were scattered through the kidney. The right kidney was small, hard, and contracted, and one or two minute calculi were found scattered in its substance. There was no calculus in either ureter, and no other cause of ureteral obstruction present. It is argued from such a case as this that the surgeon may be easily misled by clinical symptoms, and also by abdominal exploration, to operate upon the wrong kidney, viz., one which, though the seat of a calculus, is not the organ which is exciting the present symptoms, these symptoms being caused by the second kidney having become calculous after it had undergone hypertrophy owing to previous long standing calculous disease in the first. Such cases are not favourable for operation, and differ vastly from the more numerous cases which are *cured* or *relieved* respectively by nephrolithotomy and nephrectomy.

Mr. Henry Morris on

A CASE OF SUCCESSFUL NEPHROLITHOTOMY.

A man, æt. 42, who for ten years had been suffering from symptoms pointing to renal calculus, was sent to Mr. Morris by Dr. Geo. Johnson on May 4th, 1886. He was admitted into the Middlesex Hospital on May 12th, and operated upon on May 15th. A rough rounded calculus, weighing 23½ grains, was removed through an incision in the loin from the right kidney. There was no pus in the kidney. After the operation no urine whatever escaped by the wound, but blood in decreasing quantity was passed in the urine for some days. The wound healed by direct union. The patient sat up on the sixteenth day, and was discharged perfectly well at the end of the third week after the operation. For a long time prior to coming under notice he had taken very large quantities of brandy and laudanum to relieve pain; these were entirely discontinued from the time of the operation, as all his pain ceased from that time. He has been several times seen since he left the hospital, and is in good health and passing perfectly natural urine.

Mr. **Howard Marsh** on

A CASE IN WHICH VERY SEVERE SYMPTOMS WERE DUE TO TWO SMALL STONES IN AN ATROPHIED AND MOVABLE KIDNEY—FAILURE TO DETECT THE ORGAN BY AN ANTERIOR LUMBAR INCISION—DISCOVERY BY LAPAROTOMY—SUCCESSFUL REMOVAL OF THE KIDNEY.

E. D., æt. 25, unmarried, was admitted into St. Bartholomew's Hospital on June 29, 1886, with well-marked symptoms of stone in the left kidney—constant pain, severe exacerbations, frequent micturition, and pus and blood in the urine. As no improvement followed rest and medical treatment, it was determined to explore the kidney. For this purpose an incision, suggested by Mr. Willett, and which had several times been found highly advantageous for the removal of large kidneys, situated exactly half way between the spine and the middle line in front, and vertical in direction, was made through the abdominal wall and fascia transversalis. The kidney, however, could nowhere be found, though a wide search was made. On a subsequent occasion the abdomen was opened in the middle line, and the hand passed in. The kidney was now easily detected, but found to be movable and atrophied. No stone, however, could be felt. The kidney was then removed by the ordinary lumbar incision. The patient made a bad recovery. On opening the kidney after removal two oz. small stones were found in one of the calices. The author drew attention to the important fact that, though the symptoms were very urgent, the stones on which they depended were of very small size. He pointed out that, though the incision on the axillary line is ordinarily adopted for the removal of a large kidney, the posterior lumbar incision is preferable for the purpose either of mere exploration or the removal of a stone from the kidney; and he discussed the means that may be adopted for the detection and removal of small renal calculi. He also raised the question how far the symptoms in the present case may have been due to the fact that the kidney was freely movable.

Mr. **William K. Bennett** on a case of

SUPPOSED NEPHROTOMY FOR SCROFULOUS DISEASE.

L. F., a married woman, æt. 37, was admitted into St. George's Hospital under the care of Dr. Champneys on December 25, 1885, on account of abdominal tenderness, painful micturition, and a reniform swelling on the left of the navel, which rapidly increased, and by Jan. 8th extended into the left loin. On Jan. 14 there was a sharp rigor, fluctuation became manifest in the mass, and a considerable amount of pus appeared in the urine, which was neutral in reaction, and up to this time had only been slightly turbid. Exhausting vomiting set in, and the case was transferred to Mr. Bennett's care who, on Feb. 3rd, laid open the tumour freely through the left loin whereupon a large quantity of curdy, partly caseating discharge poured out, with a foul urinous odour. On the finger being introduced into the cavity it entered what was apparently a disorganised scrofulous kidney, there being a large sac with irregular imperfect septa formed, so far as could be judged, by the undestroyed calices running in the usual direction. At the inner aspect was a pouch-like off-shoot which was thought to be the dilated ureter. Great relief followed the operation, the patient was progressing favourably in every respect; the abscess contracting rapidly until Feb. 18th when lung complications set in, of which she died on Feb. 28th. *Post-mortem Examination.*—There was a small wound in the left loin leading into a sacculated abscess of small size, at the inner and anterior part of which lay the kidney *absolutely intact*, not having been involved in the operation at all. The organ, on being cut open was found in a condition of scrofulous disease, but had not broken down to any extent. Difficult as may be the differential diagnosis of renal and peri-renal abscess, Mr. Bennett was unacquainted with any case in which doubt had arisen, after free incision, as to the situation of the disease. In his case so exactly in every way did the cavity resemble the interior of the kidney at the time of operation, that no surgeon could have doubted that the kidney had been laid open. Had the patient survived as she might have done, but for the occurrence of lung disease, the abscess would certainly have healed, and the case probably have been recorded as a successful instance of nephrotomy for scrofulous disease. As it seemed not impossible that similar sacculated abscesses may have been opened by other surgeons under the impression that the kidney had been incised, Mr. Bennett thought the case not without interest in connection with the statistics of the results of treatment of scrofulous kidney by incision.

In consequence of the lateness of the hour, the discussion on these papers was postponed until the next meeting.

LIVING SPECIMENS.

Mr. **Godlee** showed a man in whom both superior maxillary bones had been removed for epithelioma of the hard palate.

Mr. C. R. **Lunn** showed

1. Case of Raynaud's disease of feet.
2. Case of myxœdema.
3. Peculiar deformity of the foot in an ataxic patient.
4. Case of icthyosis.

Mr. R. W. **Parker**, an unusual form of harelip.

Mr. **Morris** cases illustrative of successful nephrolithotomy, together with calculi removed from the kidney in four other cases.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Meeting held January 20th.

The President, Dr. **Cleaver**, in the Chair.

Dr. **Law** exhibited some specimens of

ENLARGED SPLEEN.

One was from a girl, æt. 8; enlargement of the abdomen was first noticed three years before. The other was from a man, æt. 37. The spleen weighed 3½ lbs. That from the child was not much less. In neither case was there any history of intermittent fever; but there was well-marked leukæmia in each instance.

Specimens were exhibited by Mr. Baldwin, Mr. Snell, Dr. Dyson, and Dr. Cleavers.

Mr. J. **Williams** read a paper on

THE ETIOLOGY OF GOITRE.

In it he reviewed the various theories which have been advanced as to its causation. Amongst the theories he particularised were:— 1. Snow water; 2. Indigenous to mountainous districts; 3. Geological formation of the districts affected; 4. Diminished atmospheric pressure; 5. Carrying weights on the head; 6. Some form of iron in the drinking water; 7. Want of proper sanitary surroundings, and all causes which serve to depress vitality. In the course of his remarks, he mentioned his experience as to the prevalence of this disease in Novi Bazar, or as the Turks call it, Yeni Bazar, where he was in 1876. Half the population seem to be affected, of both sexes and of all ages. Against the idea of snow-water, Mr. Williams places the fact that goitre does not occur in Lapland or Greenland, where snow-water abounds. Against its being indigenous to mountainous districts, stands the fact that it occurs in the plains of Lombardy, and other low-lying countries. Reviewing Dr. Thursfield's theory as to the effects of weights being carried on the head, he thinks the fact that in South Wales, where this habit is widely practised, there are remarkably few cases of goitre, is sufficient to show that it is an unsound one. In Novi Bazar, where so large a proportion of the population suffer from goitre, it is not a universal practice to carry weights upon the head, another reason for objecting to the theory. Indeed, comparing the conditions existing in South Wales and at Novi Bazar, *i.e.*, on the one hand, diminished atmospheric pressure and weights carried on the head, with an extremely rare occurrence of the disease; and, on the other, ordinary atmospheric pressure and no weights carried on the head, with the existence of a very large number of cases. Mr. Williams does not see how, for one moment, such a theory as that of Dr. Thursfield's can be maintained. Mr. Williams favours the idea of some substance contained in the drinking water being at fault; some form of iron or other element, further favoured by want of proper surroundings on the part of those affected, and of proper sanitation. It evidently occurs most in those districts where the magnesian limestone abounds, and in some form or other, is frequently found in combination with this formation. In connection with this view, he quoted Dr. Giles' (of the Indian Medical Service) paper upon "Goitre in the Himalayas.' Dr. Giles says that "the disease is most prevalent where granite and gneiss abound, where timber is scarce, and where the natives live in a state of dirt and darkness, and absence of all proper sanitary surroundings." These same conditions occur at Novi Bazar. Mr. Williams believes in heredity, and quotes the opinion and experience of Dr. Allen Thomson Sloan to this effect.

A discussion followed, in which Dr. Dyson, Dr. Law, Mr. Aitken, Mr. Browning, and Mr. Baldwin took part.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

January Meeting.

The President, I. Mossop, Esq., in the Chair.

CASE OF OSTEOTOMY.

Dr. **Rabagliati** showed a case of restoration from extreme knock-knee by osteotomy. The malleoli were 10½ inches apart, the right malleolus being 5½ inches from the perpendicular and the left 4½. After recovery from the operation, the legs had become almost perfectly straight—the right thigh only being somewhat bowed, without however affecting the straightness of the foreleg—both malleoli could now be brought into contact. The patient was in the Infirmary about 4 months, two operations being performed. Dr. Rabagliati said he had now done a great many of these operations which he thought it best to perform when the patient had attained some age and consolidation of the bones was likely to be permanent.

Mr. **Appleyard** said that many surgeons objected to this operation as the legs could be straightened without it; he was not of opinion that this could have been effected in Dr. Rabagliati's case, he himself, had done about a dozen cases with good results. He had met cases in which the children's bones were very hard, and could not be straightened by pressure.

Dr. **Bell** inquired whether any of the cases operated upon by Dr. Rabagliati had lapsed back into deformity.

Dr. **Rabagliati** in reply, said that it was fear of this result which made him choose cases that had attained some age. He had had a case of a child which lapsed again into crookedness but it could be operated upon again. No bad results followed these operations

Mr. R. H. **Meade**, F.R.C.S., then read a case of

AMENORRHŒA FROM OVER BRAIN-WORK, FOLLOWED BY ATROPHY OF UTERUS.

In 1886, he was consulted by the mother of a young lady, who said that her daughter had not menstruated for about 3 years, she was 18 or 19 years old, and had been quite regular and healthy for about 2 years, until at the death of her father she was obliged to engage in teaching. She was very energetic about it, and anxious to do what she could for her family, and overtaxed her brain, in consequence of this she became nervous and hysterical, stopped menstruation, but did not become anæmic nor generally out of health. Her manner and temper got queer and irritable, and on account of these symptoms she was recommended to undergo the massage treatment, under Dr. Playfair. She stayed sometime in London and derived great benefit mentally from this plan, but menstruation did not return, she however was well enough to resume her studies and teaching, and went on well with the one exception for a long while. The amenorrhœa continuing, she was advised to consult someone in Manchester who recommended stimulating applications to the uterus itself. Before she tried these, her mother brought her to Mr. Meade, and wished to have his opinion respecting them, who thought it necessary to examine the uterus before deciding. She was now in good general health, eating well, plump and not at all anæmic, and naturally healthy. Upon making a digital examination, he found the uterus both the cervix and body, *very small*, evidently atrophied, and told her mother that he thought fresh treatment of no use, and advised that all remedies (she had taken iron, aloes, hellebore, &c.) should also be let alone. The chief interest in this case was the fact that over excitement, in the way of learning seemed to have the power of interfering with the healthy functions of the generative organs, and therefore it became a serious question whether girls' brains should be over-taxed. Amenorrhœa was very common among school girls, though it did not often lead to serious mischief, and teachers and governesses were often very irregular as to menstruation. He saw another some what similar case a few years ago, a young lady 17 or 18 years of age, began with amenorrhœa while at school in Germany, and for 3 or 4 years after, nothing would bring menstruation on again. She was not anæmic, but got into a queer mental state and would not eat; she also went under the massage treatment, and afterwards took a voyage to Australia, by means of which her health and mind improved, but when he last saw her there had been no return of menstruation. He had no opportunity here of making an internal examination, but suspected that a similar state of uterus was present.

Dr. **Goyder** said that this case raised an important issue, and forcibly illustrated the baneful results of overtaxing the nervous energy. Here the mischief was not in the over-pressure of school children against which the medical men of Bradford had lately raised their voices, but it was in the over anxious and over-wrought teacher, the result was to unfit the woman for married life; practically to unsex her so far as procreation was concerned. While therefore the higher culture of woman should be cared for, was not the assumption of the function of the man, taking the woman out of her rightful sphere, and depriving her of her proper place and power in social life ?

Dr. **Rabagliati** followed on the same lines.

Dr. **Bell** said he had had a good deal of experience in amenorrhœa, the cases differed as to their causes in different classes of the population, but were quite amenable to treatment, if the causes were as far as possible removed, the function could be restored by stimulation and exercise; the introduction of a stem pessary would effect this, and increase of the size of the uterus.

Dr. **Hime** said he was not disposed to think Dr. Bell at fault in general treatment. Every practitioner knew that most cases of amenorrhœa were temporary, but this was very different from the extreme results in Mr. Meade's case, where over-pressure of brain was clearly the cause of the mischief. He had known many cases in which the intellectual powers had been exercised to the great detriment of the physical, and to the introduction of serious interference with the normal, functions of the uterus.

Mr. J. **Appleyard**, M.B., F.R.C.S., Surgeon to the Bradford Infirmary, then brought before the Society a series of interesting cases from hospital and private practice, which will be found under "Clinical Records," page 95.

In the discussion that followed the reading of these cases,

Mr. **Meade** said that epithelioma was the most hopeful form of cancer. He had seen many cases of the lip operated upon, the patients remaining well for years. The penis was a favourable organ for removal, because you could remove the whole of the diseased structure. He strongly felt that cancer was a local disease in its early stage, and that if perfect recovery was to be secured it should be removed as soon as discovered.

Dr. **Hime** inquired with regard to the swallowing of the pin, what diet had been enjoined. He ordered a diet which would produce solid motions. Was the larynx examined in the case? With reference to cancer, he thought late operation advisable for the relief of symptoms where early removal had been neglected.

Mr. **Barber** mentioned a case in which a hook had been caught in the larynx, it could not be discovered during life, but was found on a post-mortem.

Dr. **Rabagliati** mentioned a case in which he had turned a woman upside down, and dislodged a ring which had got into the larynx. As to the local or general character of epithelioma, this was a point for discussion. Its progress was generally inversely as the age, with the old it was slow, hence he would operate at once on the young. His experience of mammary amputations for cancer during the period he held the house-surgeoncy in the Bradford Infirmary was that every case died of general cancer within four years of the mammary operation.

Mr. **Appleyard**, in reply to Dr. Hime, said he gave opium and solid food in all cases in which foreign bodies were swallowed. The laryngoscope could not be used in so young a child. In cancer he did not advise operation when there was ulceration. He had seen rapid death after operation in such cases.

The proceedings then terminated.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 2, 1887.

CONVALESCENT FEVER HOSPITALS.

A very sharp and, it may be, bitter contest is imminent amongst the members of the Metropolitan Asylums Board as to the desirability or not of opening the large convalescent fever hospital that has been built at Winchmore Hill for the reception of such cases. Strong difference of opinion exists among the managers, who are divided into two parties, each with its own policy distinctly formulated. And in each case, the policy as to the Winchmore Hill Hospital is determined by attitude to the Darenth Convalescent Small-pox Hospital question, with which, indeed, it is inseparably bound up. The one side wishes to build a convalescent Small-pox hospital at Gore Farm, near the Darenth Asylums, to make use of the Northern Hospital (Winchmore Hill), now that it is finished, for convalescent fever cases, and to keep Stockwell and Hampstead Hospitals still closed; the other side desires to use part of the Darenth Asylum for convalescent Small-pox, to transfer the asylum patients thus ousted to Winchmore Hill, and to reopen either Stockwell or Hampstead for acute fever cases. The latter party, it will be seen, are the sticklers for economy, wishing to make use of the present provision of the Board, without incurring further outlay; the former contemplate building an additional hospital, using the Northern for its originally intended purpose, whilst still keeping only three of the five acute hospitals of the Board open for the reception of cases. With this divergence of views, and in the absence of a properly constituted medical adviser to the Board, the managers have addressed a circular letter to the medical superintendents of their different fever hospitals, asking for their opinions upon the subject. We are not concerned with either the views or the replies of these gentlemen, neither can we pretend to pronounce upon the general policy of the Board itself, whether, for instance, economy only is to be thought of, or efficiency alone, or whether a judicious blending of the two should not be earnestly sought for in the settlement of a question affecting the health, no less than the pockets, of the London rate-payers. But what we can attempt to do is to examine the abstract question as to whether a convalescent fever hospital is absolutely necessary, or even desirable, for the patients in the Asylums' Board Hospitals. Now, it is certainly customary for parents who can afford it to send their children to the sea-side or to the country after scarlet fever; and there are several homes which receive middle-class patients on payment of small sums. But we are doubtful if, in the majority of uncomplicated cases, much real benefit is derived from such a course of proceeding, unless the patient's surroundings during the acute stage have been unsatisfactory. Then, and then only, is there any real need for convalescence in the country or at the sea. Where a private patient has abundance of fresh air during the acute period, is well oiled and bathed, and has plenty of sound nourishing food, and where also, he has means of taking gentle exercise during desquamation, in such a case we maintain that sending him away to the coast or inland is futile and unnecessary. On the other hand, a petty tradesman's child, say, in a crowded neighbourhood, treated in the back parlour by a third-rate practitioner, would derive great benefit from three or four weeks at Miss Wardell's Home. Now, under which category do the patients at the Asylums Board Hospitals come? The answer to this will be found in reference to the well-situated, well-appointed hospitals of that Board, where ample cubic space is provided during the acute stage, bathing and food are constant and good, and where during desquamation, ample airing grounds are provided for patients. The condition of the greater part of the cases on their discharge has only to be seen to make the conclusion still more decisive that for the majority of scarlet fever cases in these hospitals, a convalescent hospital is unnecessary and undesirable. We should speak, however, with more reserve with respect to those cases which are detained longer than the usual eight weeks, on account of kidney mischief, general debility associated with large enlarged glands of the neck, and with strumous discharges from the ear and nose. For these, we are of opinion that a residence for several weeks exposed to fresh country air would expedite recovery, and be of great advantage to each patient. For these, and these only, amongst scarlet fever cases would we advocate the opening of the Northern Hospital at Winchmore Hill, with the consequent expense attached to such opening. As to enteric fever patients, we consider that convalescence passed at such a hospital would be decidedly shortened, but great care would have to be exercised in the selection of cases for transfer; and there is not a large number to select from. These seem to be some of the considerations which strike us on cogitating over this matter of convalescent hospitals for fever patients; and in giving vent to them, we must not fail to express our sympathy with the Asylums Board in their endeavours to find a solution to the problem, "What is to be done with Winchmore Hill?" For it must be always remembered that this colossal institution was built in close pursuance of the recommendation of the Hospitals Commission of 1882, which advised provision of a maximum of 3,000 fever beds (half in town and half in the country), a calculation which appears to us to be based far too high, in view of the number of cases treated in the Board hospitals of late years.

THE STATUS OF THE IRISH APOTHECARIES' HALL UNDER THE NEW MEDICAL ACT.

The relation of the Apothecaries' Hall to the Irish Conjoint Examination now being organised has been already hotly discussed, and is certain to be the subject of anxious and prolonged debate in the approaching meeting of the General Medical Council, and it will, we think, be advantageous for us to recapitulate briefly the circumstances which placed the "Hall" in its present position as a licensing body.

The Irish College of Physicians has prepared a formidable manifesto for presentation to the Council, the object of which is to prove by legal opinions and other aguments, that the "Hall" is not, and never was, lawfully authorised to grant licenses to practise medicine, and that, being incompetent to do this, it is necessarily prohibited from availing itself of the third clause of the new Medical Act and from continuing to grant such licenses, either in conjunction with another body or independently. We are in a position to publish this manifesto, but as the College of Physicians pleases to regard it as, for the present, confidential, and has officially declined to give us a copy, we are precluded from making known its contents, except so far as they are generally spoken of.

As to the original status of the Irish Apothecaries' Hall, there can hardly be any doubt that that institution was neither intended to be, nor until the year 1858 had any pretensions to be, a medical licensing corporation. Its functions were very clearly defined by the Act which erected it (31 Geo. III, cap. 34), and the reasons given in the preamble of that Act for its incorporation were:—1. "The want of a Hall amply supplied with medicines of the purest quality." 2. The necessity for inspection of drugs by "persons well skilled in the art and mystery of such preparations;" and 3. "The prevalence of frauds . . . practised on His Majesty's subjects . . . by the ignorance and unskilfulness of divers persons pretending to the art and mystery." It was, therefore, enacted that there should be established "a company or fraternity of judicious apothecaries, well skilled in preparing and compounding of medicines." A Board of Directors was created "for inspecting and directing all chemical and compound preparations." Every apothecarry was authorised to take apprentices "to prepare or vend medicine," and it was provided that none should "open shop or act in the mystery of an apothecary, until he should be examined as to his qualification and knowledge of the business." In no part of the Act is there one word which—even by the broadest interpretation—could imply any right in the "Hall" to examine in medicine or surgery, or to license anyone to practise such profession in any way whatsoever.

This Act is the only charter of the "Hall," and that institution could possess no other right or privilege except those thus conferred, unless such additional rights were granted by another Act of equal force. Up to the year 1858, therefore, all the pretensions of the Hall, however clamorously insisted on, were futile, and the privileges which it usurped the right to confer were of no validity whatever. But in 1858, the Medical Act passed which at once placed the "Hall" in a new position. Its name was placed, in perfect equality, side by side with those of the acknowledged Medical and Surgical Corporations, and by the inclusion of it in the schedule of the Act it was admitted to every right granted or confirmed by that Act. There is not a word in the Medical Act of 1858 to suggest a doubt that the "Hall" was not fully recognised as equivalent in function to the other Corporations; since that date, many Amendment Acts have confirmed it in that position, and now the Medical Act of 1886 has continued to it all the privileges which it previously possessed.

How do these Medical Acts define the privileges of a Licensing Corporation? Clause 15 says: "Every person becoming possessed of one. . . . of the qualifications described in Schedule A (which includes the L.A.H.) shall. . . . be entitled to be registered;" and Clause 31, declares the functions and rights which such registration confers, as follows: "Every person registered under this Act shall be entitled according to his qualification or qualifications to practise Medicine or Surgery, or Medicine and Surgery, as the case may be, in any part of Her Majesty's dominions, and to demand and recover in any court of law, with full costs of suit, reasonable charges for professional aid, advice, and visits, and the cost of any medicines or other medical or surgical appliances rendered or supplied by him to his patients."

The only words of any ambiguity in this Clause are: "According to his qualification or qualifications," and this phrase has been pleaded in law courts, but ineffectually, to prove that a singly-qualified surgeon cannot recover fees for pure physician's work, but however this may be, it is clear that every license scheduled in the Act including the L.A.H. confers the right to practice one or both of the specialities, medicine and surgery, and the only question which can arise is as to which the L.A.H. represents.

Thus, the legislature deliberately, if not wisely, extended the functions of the Irish Apothecaries' Hall, and it did so, notwithstanding the earnest protests of the Medical and Surgical licensing bodies. But when the "Hall" had acquired these privileges, it became necessary, in order to obtain the *usufruct* of them to satisfy public departments of the fact, and accordingly, the "Hall" forthwith addressed a letter to the Army Medical Department pointing out that it was now qualified to grant the medical license required from assistant surgeons. On the 16th of August, 1860, the Director-

General sent a letter on to the General Medical Council with the query "whether the license of the Hall entitles the holder to be registered under the Medical Act as a practitioner in medicine," and, not having elicited a conclusive reply, repeated the query on the 22nd of June, 1861. It was therefore moved by Mr. Syme, and seconded by Dr. Leet, that such person "is legally" entitled to "do so." To this, two amendments were moved: 1. Stating that "the Council having heard contradictory legal opinions on the questions, . . . respectfully decline to pronounce an opinion." 2. That "considering the probable intention of the Legislature, . . . the Council are of opinion that it would be in accordance with the spirit, and meaning of the Act to consider the said licentiates as legally qualified practitioners of medicine." The amendment which declined to express any opinion was carried by thirteen votes to eight.

At the succeeding meeting in 1862, a motion was made to take a law opinion on the subject, but the proposal was negatived. A year later, in June 1863, the question was at last settled. It was then moved that Licentiate Apothecaries "are entitled to practise Medicine," to which an amendment was moved that the Council having already had the question many times under consideration declined "to re-open the question" but that "the conflicting legal opinions be sent to the Director-General." The original motion was carried by a vote of 13 to 8, and then the Council put its seal upon the interpretation of the Medical Act, which the Apothecaries' Hall depended upon to establish its *status* as a licensing corporation. Such is the history of the consolidation of the Irish Apothecaries' Hall as a Medical Licensing Corporation, and it appears to us scarcely *ad rem.* to discuss now—as the College of Physicians proposes to do—the primitive rights of that body, any more than it is relevant to debate the rights of present landowners to the properties which were confiscated for the benefit of their ancestors some hundreds of years ago.

We know that the pretension of the Apothecaries' Hall to license doctors was a usurpation—that the recognition of that pretension by Parliament was unjustifiable and unwise; and that the verdict of the Medical Council in 1863 was little better than the declaration of an interested cabal, but nevertheless that verdict was final, and, if it were ever to be reversed, the College of Physicians has lost its chance in having, notwithstanding our warnings, permitted the Medical Act of 1886 to pass in its present form. To attempt, after the lapse of six and twenty years, to fall back upon the old argument is puerile, and the College is simply wasting the time of the Medical Council in provoking a debate on a controversy which has been, long since, dead and buried.

It is much to be regretted that the College of Physicians has shown itself incapable of discerning the wisdom of accepting the inevitable—that it has forgotten that the world and public opinion has grown thirty years older, and that it has by its obvious incapacity to release itself from tradition, accepted the opprobrium of being the obstinate and impracticable element in the settlement of the medical future of Ireland.

◆

ETHICS OF OUT-PATIENT PRACTICE.

For some occult reason the Medical Committee at the Westminster Hospital have thought desirable to promulgate the following resolution which was endorsed by the House Committee:—

"That the Medical Committee view with disfavour the practice of seeing the out-patients in numbers in the same room at the same time, as being both undesirable and improper; but consider that, whilst as a rule the patients should be seen singly, it may be quite admitted that occasions may arise in which for special reasons two, or most exceptionally three, patients should be in the consulting room at the same time."

It would be interesting to be informed what train of circumstances rendered such an injunction necessary. Had any member of the staff been in the habit of seeing patients of different sexes at one and the same time? We are far from thinking such a rule inappropriate, although doubtless there are circumstances under which prudence would indicate the presence of more than one patient at a time. It must certainly be unpleasant to patients of either sex to be called upon to unfold their story before an unsympathetic, if not indifferent audience of fellow-sufferers. If any disproportion exist in their ages it even becomes demoralising.

As a matter of fact, however, out-patient practice, as at present carried out in metropolitan hospitals, would be impracticable were this rule rigidly enforced. It may be urged of course that this is in itself an argument against the present system, but even if this be admitted, so long as it remains in force, it has to be carried out the best way it can be. In some institutions a nurse attends the out-patient department, but except possibly where children are concerned, her assistance may advantageously be dispensed with in favour of a dresser.

Imperfect as is our English method of conducting the out-patient department of hospitals, it is, with all its inconveniences and shortcomings, infinitely superior to that which obtains in most continental cities,and especially in Paris. There the crush is so great, and the time allowed so short, that the "consultation" consists mainly in the distribution of prescriptions written beforehand without more than a simulacre of examination or diagnosis. It is only inside the hospitals that their condition is seriously gone into, and even there, in the majority of cases, our kindly if costly hospital management, leaves them far in the rear. Hospitals in Paris are affiliated to the institution which represents to some extent our Poor-law arrangements, and this may account for the difference, although the comfort of patients in the workhouse infirmaries of this country leaves little to be desired.

◆

The nineteenth anniversary dinner in aid of the funds of the French Hospital and Dispensary is announced to take place, at Willis's Rooms, on Saturday next, the 5th inst. His Excellency the French Ambassador will take the chair, and will be supported by the Lord Mayor and the Sheriffs and Under-Sheriffs of London and Middlesex.

Notes on Current Topics.

The Inquiry at Mercer's Hospital.

It will be readily understood that we have no desire to express any opinion or take any side in the public controversy which took place last week as to the management of Mercer's Hospital. We refrain—Firstly, because we cannot see that questions of hospital administration—outside their medical aspect—are any business of ours. Secondly, because the case is *sub judice*, and it would be an impropriety to express an opinion until a judgment is arrived at. But we do not think that we prejudge the matter in dispute in any way by criticising the proceedings of the Committee of Inquiry appointed by the Dublin Corporation to investigate these matters, in which function, in our opinion, they have covered themselves with discredit, and greatly damaged the cause of the hospital executive.

The Corporation was invited by the hospital authorities to hold an inquiry, and therefore nominated a Committee, the *personnel* of which was obviously weak, both in numbers and in judicial capacity. The Committee sat with closed doors, and nobody knows whether or not their method of inquiry was impartial, or what evidence was heard; but the outcome has been a whitewashing of the hospital administration and administrators so elaborate and unstinted that no one who reads the verdict can suppose it to have been arrived at in a perfectly impartial spirit. The Corporation Committee do "protest too much." Not only do they declare the hospital management free from blame as to the occurrences in question, which it may probably be, but they go on to pronounce its administration to be as nearly as possible perfect, whilst the decadence of the institution within the last three years sufficiently proves that it is not. They had, they say, "no difficulty or hesitation in coming to a unanimous conclusion," *inter alia*, that the man who was alleged to have been maltreated, "received proper care and attention," that, "so far as the statement that the man received brutal treatment is concerned, the evidence establishes that the instructions of the physicians were carried out with anxious care by the resident surgeon and the matron." We do not suggest that these conclusions are incorrect, though, indeed, they read very strangely alongside the evidence in the police court upon which the resident surgeon has been committed for trial for manslaughter. We are, however, obliged to say that the Corporation Committee would have acted much more discreetly if they had declined to hold or proceed with inquiry when most of the matters to be investigated were already under examination in the police court. But if they thought it fit to hold the inquisition, they should have treated the evidence with perfect impartiality, which—on their own showing—they did not do, for they state that "to the testimony of other witnesses (for the accusers) the Committee did not attach weight, it being that of servants whose services to the hospital had been discontinued." It seems to us that the evidence for a complainant must, in many cases, be that of persons who, having ceased to be connected with the institution, are free to speak the truth without apprehension of dismissal, whilst that for the defence, given by the officials, should, for the opposite reason, be accepted subject to, at least, as large a discount. The final paragraph of the Committee's report goes so far beyond the subject matter of the inquiry, and is in such a spirit of gushing laudation of the hospital, its work, its management, and its officers, that one is tempted to ask whether there is, in the eulogium, any personal influence, or why it is that the laudatory report was received by the Corporation with a unanimity of rapturous approval which, in that assembly, is a rare phenomenon. One conclusion from the whole transaction is inevitable. Either the report of the Committee or the evidence before the police magistrate is false, and, no doubt, when the subject comes before a jury we shall be able to make a choice of these alternatives.

Hydrophobia.

Much of the confusion which has arisen since M. Pasteur's claims have been so fully discussed arises from our inability to define what is the disease called hydrophobia. Its course and symptoms vary so greatly, and the post-mortem appearances are so uncertain, and even negative, that until some light is shed on these vexed questions, little real progress can be hoped for. The statistics, again, have been manipulated in so many different ways, and made to prove so many different theories, that even the scientific investigator is apt to give up in despair his attempt to arrive at even an approximate opinion on the subject. The ignorance of most veterinary surgeons and medical men as to even the accepted symptoms of hydrophobia is simply phenomenal; nor can it well be otherwise, seeing that most men pass through life without meeting with a case. To argue, therefore, that the disease transmitted was hydrophobia is like discussing whether a certain versifier is or is not a poet without defining in the first instance what constitutes a poet. It has generally been believed that dogs affected with rabies inevitably died, and Pasteur affirms that they die within ten days. If this be true, then a great many cases of alleged hydrophobia are wrongly diagnosed, even if we allow for the large number of instances in which the stupid plan is adopted of immediately killing the animal. Dogs are liable to forms of cerebral excitement, and even dementia, quite independently of rabic influence, and this fact vitiates the value of any statistics unless the protection is absolute, *i.e.*, without an instance of the disease having subsequently supervened where inoculation has been performed within the prescribed limits of time.

The Metropolitan Hospital Sunday Fund.

A meeting of the Council of the Hospital Sunday Fund was convened last week to consider a letter from the Bishop of London, in which he proposed to alter the date of the Hospital Sunday this year from the 19th June to the 3rd July, on the ground that the several church services intended to celebrate the Jubilee of Her Majesty would seriously militate against the success of the Fund. After a prolonged discussion it was resolved to adhere to the date originally fixed for the collection. The following resolution was also carried:—"That in view of the approaching Jubilee, and to meet the urgent needs of the poor who are being relieved at our hospitals, it is desirable at once to make strenuous efforts to largely increase the Hospital Sunday Fund collection of 1887, and that a special committee be appointed to carry out these views." It was urged that the financial condition of most of our hospitals is in an unsound state, and towards the end of the year might be expected to be some £70,000 or £80,000 to the bad. On this account we regret that no member of the Council proposed to appoint a committee to confer with the managers of hospitals and devise a means of placing a check upon the indiscriminate abuse of medical charity. A very large number of undeserving people are constantly assisted in the out-patients' department: the Executive, however, make no effort to deal with the evil, because it is believed and known that a *grand total* has an imposing effect, and will be sure to increase the subscription list. We have always contended that the indiscriminate bestowal of medical charity has a pauperising effect upon the people, and is undoubtedly as injurious in a public point of view as in a professional.

Phthisis in the Army.

An interesting paper recently read before the Statistical Society, by Inspector-General Lawson reveals some very striking and interesting points in connection with the extent to which phthisis prevails among our land forces. It may be in the recollection of our readers that the Royal Commission of 1858 laid great stress upon imperfect ventilation of barracks as being an important item in the causation of that disease; but statistics seem to indicate that improvements which have of late years been effected in that respect have had less to do in reducing the incidence of phthisis than might naturally have been looked for. That soldiers still continue to suffer more from consumption than corresponding classes and ages in civil life is unquestionable. The more general adoption of flannel underclothing, and other improvements that have taken place in uniform have no doubt tended to bring down that prevalence to some extent; but when it is observed that they have to undergo their chief exertion at drill in complete dress; that when drill is over accoutrements and coats are immediately cast off, and their further avocations usually carried on regardless of whether the underclothing be soaking with perspiration or not, while individual men expose themselves recklessly in that condition to currents of cold wind that sweep along corridors and passages—ample cause is thus provided for the extent to which mortality and invaliding by consumption continue to thin the ranks of our battalions. It is satisfactory to learn that from 1880 to 1884 a decreased rate of mortality from phthisis has taken place not only in the army, but generally in the civil population of this country.

A meeting of the friends of the late Dr. Walter Moxon, of Guy's Hospital, was held at the Royal College of Physicians yesterday (Tuesday), under the presidency of Sir William Jenner, Bart., for the purpose of initiating a movement in favour of a "Moxon memorial" of the deceased popular physician.

Syphilis and Wet Nurses.

The liability of wet nurses to transmit the syphilitic virus to the children under their care or *vice versâ* has been fully recognised, and inquiries are generally instituted by the family medical attendant with the view of eliminating any danger of the nurse being the subject of syphilis. According to a recent paper on the subject by Prof. Fournier, of Paris, the most careful and minute investigation may fail to reveal the existence of a positive danger, from the fact that at the moment of examination the disease may be in the incubation period. That the risk is not an imaginary one is shown by Dr. Fournier's observation that he had observed no less than fourteen of such cases, in which infants had become infected by nurses who were in perfect health at the time of their engagement. One of the cases was very instructive. A peasant woman in excellent health was placed in charge of an infant who developed unmistakeable signs of secondary syphilis to the effects of which indeed it soon succumbed. The nurse, thus placed at liberty to seek another infant, did so at once, and after passing the official medical inspection, was placed in charge of child No. 2. Some few days later a chancre formed on the nipple, followed in a week or two by one on the child's upper lip. When the nurse developed secondary symptoms the parents of the child discharged her and engaged a second nurse. When the infant in its turn had secondary symptoms, the medical man who was called in at once diagnosed the circumstances of the case, but not in time to prevent the infection of the new nurse. The Professor advises parents not to engage a nurse who has given the breast to other than her own children, or, if this cannot be insisted upon, to require her to produce a medical certificate that the child last suckled was suffering from no infectious or contagious disease. The matter, possibly possesses less importance in this country than in France, where the substitution of wet nurses for maternal care is almost the rule in well-to-do families. The consequences however are so terrible that Professor Fournier has rendered public service in calling attention to the possibility of contamination even with a woman presenting every outward and visible sign of health and strength.

Artificial Fecundation.

The practice, or at any rate the procedure, is one which is as old as the hills, but notwithstanding its antiquity, it has never fallen into the domain of general practice. In Great Britain, at any rate, there are very good reasons for considering any method except that which is consecrated by immemorial custom, of adding to the population, as superfluous to say the least of it. In other countries—France for example—where the population does not increase with a rapidity at all commensurate with its size and importance, the subject has spasmodically come to the front. Some little time ago, an adventurous student at Paris took up the question from a scientific point of view and incorporated the results of his observations and experiments in his thesis for the doctorate. It is uncertain whether it was the subject or the *modus operandi* which excited the ire of the Faculty, but in any case, the almost unprecedented course was adopted of refusing the thesis and ordering the whole of the copies to be impounded and destroyed. This unexpected result probably lessened the author's enthusiasm on this delicate subject, and doubtless taught him that, if he practice, it is not always wise to preach. Without lauding the practice, of which we must confess ourselves discreditably ignorant, we fail to see in it anything fundamentally immoral. At the same time, we may point out that experimental researches will probably fail in obtaining for the observer more than an undesirable notoriety. If the rumour, therefore, be true, that an eminent gynæcologist proposes cadging a few more laurels by a work on this subject, *à l'usage des hommes de monde*, the present opportunity is a good one to warn him of the fate which awaits him.

Medical Practice at the Cape.

If the lamentations of the *South African Medical Journal*, are to be accepted as sincere, and not merely funny, medical practice at the Cape is not an agreeable sinecure. The doctor is subjected to petty persecution if he refuse to "pal" with his patients, and when, if he be a bachelor, he ultimately takes unto himself a wife—the law only allowing one—he forthwith makes enemies of all the unmarried damsels of his district. The tone of one of the leading articles leads us to infer that the writer of it must just have been the victim of some or one of the episodes which he so graphically describes and was then taking his revenge, hoping that the pen might prove mightier than the—scalpel. It may be comforting to him to be told that even in the old country, doctors are not exempt from petty annoyances of this kind, especially in rural district. The only effectual protection against them is a cultivated or acquired indifference. It is the same in life as at school, if we "cut up rough" at the practical jokes or foolish tricks of our school-fellows, the result will be to plunge us in an ocean of trouble. We all have our cross to bear, though we are apt to think now and again that their weight has not been proportioned to our strength.

Leprosy in Japan.

From the *Sei-i-kwai Medical Journal* for December, we learn that leprosy is very much on the increase in Japan. In the opinion of those physicians who have given attention to the disease, this is due less to heredity than to the entrance of a specific germ into the system. This has been more recently exemplified in the spread of the disease in Trinidad and Hawaii. In 1859 the first cases of leprosy seen in the Sandwich Islands, occurred in the person of two Chinese coolies, and seven years later there were four hundred cases of leprosy reported in the Island of Molskai. The cause of this rapid spread was found not to be heredity, but rather the further importation of infected Chinese, and their being allowed to mix indiscriminately and immorally amongst the lower classes, and those from certain causes predisposed to take the disease. The Medical Society has taken the matter in hand and is issuing precautionary measures, and recommends in all cases cremation of the leprous dead.

A Novel Expedient.

Dr. Shustoff writes in the *Russkaya Meditsina* that on one occasion he was asked to intervene in the case of a woman who had been in labour five days. The pains had been severe at first, but latterly had ceased. Upon examination, he saw something black protruding from the anus, and on exercising gentle traction, he brought to light a sausage rather more than seventeen inches in length, and fourteen (?) in circumference. Immediately on its withdrawal, labour recommenced, and the woman was shortly delivered of a dead child. It was ascertained on inquiry, that the sausage had been introduced on the recommendation of an old woman of the neighbourhood, in order to ensure the birth of the child *per vias naturales*.

The Minutes of the General Medical Council.

The volume of Minutes for the past year is the largest ever issued by the Council. It contains, in addition to the records of the proceedings of the Council, the Executive Committee, and the three Branches, the Reports of the Visitors on the Irish Universities, and also the very elaborate and valuable statistics of qualification and registration compiled by Mr. Miller. This volume must have a place in every good medical library, even though its predecessor volumes are not there, for it contains much more extensive information than any of them.

O'Callaghan v. Vigors.

We regret to observe that the Court of Appeal has reduced the damages obtained by Dr. O'Callaghan in this case from £500 to £100. It will be recollected that Mr. Vigors—a local magnate—slandered Dr. O'Callaghan in a letter to the Carlow newspaper, in which he accused the doctor of negligence and incompetency (or words to that effect). Though we think the reduced damages quite inadequate, it is satisfactory to observe that Mr. Vigors will have the honour of paying the costs of both trial and appeal.

Military Punishments.

Step by step has the Duke of Cambridge continued to reduce the severity of military punishments during the long period His Royal Highness has been at the head of the army, until now, when, as if to add celebration to this year of jubilee, he has brought them down to the standard of common sense. There are doubtless men still serving who have a lively recollection of days, by no means long ago, when offences of what was then euphoniously called "a military nature," and bearing in themselves no *moral* turpitude whatever, subjected the unfortunate soldiers by whom they were committed to the lash, or imprisonment, and association with felons implied therein; or to such "minor" punishments as confinement to the cells, extra drill, confinement to barracks for a lengthened period, and so on. And there are doubtless those still in the army who also remember to what an extent an injudicious commanding officer had it in his power to literally worry and drive to desperation soldiers against whom he, or those acting under him, took what in barrack-room language was called "a grudge."

Now, we are happy to see, all that state of things is of the past, swept clean away by the latest edition of "The Queen's Regulations." As therein expressed "ignorance, thoughtlessness, temper, inexperience of the restraints of discipline may often betray a young soldier into the commission of an offence which, though technically serious, is trivial in effect;" and accordingly the Duke of Cambridge impresses upon commanding officers that their duties towards young soldiers are very responsible. Nor is it alone in respect to the military aspect of those offences that this responsibility exists. It was a fact well known to regimental surgeons that out of punishments capriciously inflicted, or out of proportion to offences committed, not unfrequently arose acts of real crime, sometimes of violence, at others of drunkenness, breaking out of barricks, *et cetera*, all of which led more or less directly to moral degradation of the individual, the disease involving premature death, or discharge to a hospital or the poor house. That these occurrences were as described is no matter of question. That they are no longer likely to happen is a circumstance calculated to enhance alike the military efficiency of our troops, their moral and their physical well-being. Surely then the term applied to another Royal Duke early in this century is more than equally appropriate to the present, for by the authority he gives to the Regulations now introduced he verily proves himself to be "the soldier's friend."

The Treatment of Asthma.

At the close of an exhaustive address on the above subject delivered before the Medical Society of Berlin on the 8th inst, the speaker, Herr Lazarus, sums up as follows:—1. The prophylaxis of bronchial asthma demands inquiry into the constitutional and inherited tendency, and especially into the disease of the respiratory surfaces of the nose, throat, and lungs. 2. The asthmatic attack itself is to be cut short as quickly as possible. Potassium iodide and chloral in equal parts in large doses once or twice a day act with the greatest certainty. In special cases operative treatment of nose and throat are to be recommended. 3. The treatment of the resulting condition is important. In general the most effective agent is the pneumatic cabinet, or potassium iodide or terpine hydrate.

The Jervis Street Hospital Ball.

We learn with much satisfaction that the promoters of this entertainment have netted, for the benefit of the hospital, a sum of nearly £700. Such a result is very creditable to their energy, and the untiring work which they devoted to make the speculation a success was rewarded by a very substantial gain to the hospital.

We see with pleasure that among the last batch of new Austrian peers, recently gazetted, is included the name of that eminent surgeon Professor Billroth. His fame is more than European, he is known and appreciated wherever surgery and surgical pathology is studied, and we are pleased to be enabled to point to his elevation as a token of the respect and honour shown to a member of our profession.

The Assistant Surgeoncy of the Dublin Metropolitan Police,

Which was vacated some weeks ago by the sudden death of Dr. P. W. Long, has been given to Dr. Henry W. Oulton, medical officer of one of the North Dublin dispensaries. The appointment is in all respects a good one, for Dr. Oulton is a worker in the profession, and not a superannuated pluralist, and is well known as an industrious and efficient public officer.

Ain-hum.

An interesting account of an affection of the toes occurring among negroes and other coloured races, and called "Ainhum," is contained in the current number of the *International Journal of the Medical Sciences.* A patient with the disease was treated in the Montreal General Hospital by the author of the paper in question, Dr. Francis J. Sheppard, whose description of the condition is taken from the appearances then observed. The disease had existed in this case for six years, commencing as a small pimple in the digito-plantar fold of the little toe. No pain or inconvenience was felt from it for a year and a half; but at the end of that time the digito-plantar fold became the seat of a constriction, and soon the toe became enlarged. Poulticing cured the sore and gave ease for a time, but later on the ulceration reappeared, pain was much increased, and the persistent furrow rapidly increased in depth. Amputation of the digit was performed, the wounds rapidly healing under iodoform dressings. Examination of the toe after removal shows a plentiful distribution of fibrous tissue, and increase in the thickness of the skin; but the alteration in the bones is the most striking feature of all. The proximal phalanx had become extremely attenuated and claw-like by atrophy, while the point between it and the succeeding phalanx had altogether disappeared, as also had that between the middle and terminal phalanges, while the latter had clearly undergone atrophic changes. The disease is very rarely encountered, and seems to have been first described in 1867 by Silva Lima, who give it an existence extending over eight to ten years, and considers that it is usually asymmetrical. Its cause is not known, but Dr. Sheppard hints at its bacillar origin, though he regrets not having preserved the specimen he removed for subsequent minute examination. Since Silva Lima's paper first appeared several cases of the disease have been reported, but so far little has been added to our knowledge of its etiology or pathology beyond what was originally described in connection with it.

The Queen is expected at Aix-les-Bains early in April for a stay of about six weeks. She will be accompanied by Princess Beatrice.

The Empress of Austria is reported to be again about to submit her Royal body to a course of massage at the hands of the prince of *masseurs*, Dr. Mezger, of Amsterdam. This gentleman is to be congratulated on Her Majesty's evident appreciation of his method of treatment.

◆

At the Societies.

MEDICAL SOCIETY OF LONDON.

Mr. Davies Colley showed (Jan. 24) a case of ectropion consequent on necrosis of the superior maxillary bone, in which he had operated with advantage. Mr. Walter Pye showed a case of excision of the elbow-joint in a lad, where partial excision had been attempted, but had failed, the lesser sigmoid cavity, which had been left, requiring to be removed five months later. Mr. G. B. Turner showed one of those comparatively rare cases of lip chancres, especial interest attaching to the case from the fact that infection had taken place at two separate and distinct places on the lip, in addition to sores on the penis. The President mercifully suggested the probability of infection having taken place accidentally by means of the fingers, and this view was supported by Mr. J. Astley Bloxam, who mentioned several cases in which he had seen simultaneous chancres at the Lock Hospital. Mr. Harrison Cripps mentioned no less than fourteen cases of chancre in unusual positions which he had observed during the past year. Mr. J. Astley Bloxam exhibited a patient on whom he had performed one of his favourite operations of plastic surgery, in which he would seem to be *facile princeps*. The man in question had had extensive ulceration of the lower part of the face, resulting in obliteration of the nose and *quasi* closure of the mouth. The orifice of the latter was restored by a simple plastic operation with the most satisfactory results. Mr. Walter Pye showed a curious case of nævus of the hand in a girl, which appeared to have a direct connection with an impression prior to birth on the part of the mother. Mr. Harrison Cripps exhibited one more instance of the good effects of colotomy in cases of carcinoma of the rectum. The patient was immediately relieved, and had very good control over the new artificial anus.

The meeting of Monday last (Jan. 31st) was entirely devoted to the reading of Dr. Langdon Down's third Lettsomian Lecture, which will be found on page 89.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The whole time of the last meeting of the Royal Medical and Chirurgical Society was spent over discussion of the treatment of hydatid cysts of the liver, the debate being initiated by Mr. Barwell. Three methods were primarily mentioned in the paper, though one was named only to be condemned as unsatisfactory, that, namely, of electrolysis. In all cases, Mr. Barwell urged, puncture with a small trocar ought first to be performed, since this operation often sufficed to cure in cases where only a single cyst existed; but when it failed through the presence of numerous daughter cysts, he advocated the making of a free abdominal incision to the edges of which the cyst should be securely stitched, and later on an opening made into the tumour itself, through which all the contents might ultimately escape. Certain necessary precautions to be observed in cases where the thinness of the cyst wall rendered effusion of the fluid into the peritoneum probable, were carefully described; and the author concluded his paper with a description of a case in which he had performed the operation after the hydatid (in a woman) had been punctured eight times previously.

Mr. Warrington Haward did not agree with Mr. Barwell's mode of directly incising the parietes, but inclined rather to the adoption of a method of gradual perforation by caustic paste, with the object of securing sufficient peritoneal adhesions. He admitted, however, that when the contents of the cyst were thick and compounded of daughter cysts a free incision might at times be required. Mr. Howard Marsh, following Mr. Haward, lent powerful support to Mr. Barwell by citing a most successful case in which he had recently followed the plan recommended by the latter gentleman; and he mentioned also another case, that of a child, in which suppurating hydatid cysts had been directly incised without any attempt being first made to secure adhesion to the abdominal wall. There was no extravasation into the peritoneal cavity, and all went well. A similar case was instanced by Mr. Harrison Cripps, who warmly espoused the method of free incision as likely to be followed generally with good results owing to the frequent complication of hydatids by multiple cysts.

Sir Dyce Duckworth and Mr. Walsham both accorded a qualified approval of the method advocated in the paper, Sir Dyce, contending that favourable results might follow after all the varieties of treatment. Mr. Walsham agreed that it was not necessary always to secure the cyst to the parietes, and thought the incision made was often needlessly long. Dr. Angel Money instanced a fatal case in which a daughter cyst caused death by escaping into the hepatic vein.

The discussion was continued by Mr. Pearce Gould and Mr. Henry Morris, the former insisting that aspiration ought first to be tried in all cases, and that caustics should give place to the knife, while on the question of stitching the cyst to the edges of the incision he sided with those who regarded it as an unnecessary proceeding. Mr. Morris dilated on the early literature of the subject, and criticised some of the views expressed by previous speakers. He condemned the too free use of iodoform as a dressing, a point on which, owing to the risks of poisoning thus incurred, Mr. Barwell quite agreed with him.

Scotland.

[FROM OUR OWN CORRESPONDENTS.]

THE PROFESSORIAL SQUABBLE AT EDINBURGH.

Referring to the extraordinary letters which appeared in our last issue from the Professor and the late Senior Demonstrator of Physiology in the University of Edinburgh, The *Scotsman* asks:—"Is nothing to be done to prevent honourable men from being defamed, insulted, and driven away from the University? Will the Senatus Academicus do nothing in the present case? For the vindication of its own honour it is surely bound to deal with the matter. . . . . It may be taken for certain that the intense feeling which this case has aroused will not be satisfied with any mere patching up of the present quarrel, or even with formally assigning blame where blame is deserved. Something more thorough and radical is called for, and that will only be found in a complete change in the status and relations of the Assistant Professors, with, of course, a corresponding change in their mode of payment. If Mr. Ashdown's case is the means of bringing about that reform his sacrifice will not have been made in vain." In opening the class of Institutes of Medicine on the morning of Friday last, Professor Rutherford addressed the following remarks to his students:—"Most of you have seen a remarkable article in a periodical which has placed me in a false light. I am not now prepared to make any statement such as I think I ought to make to my students for the purpose of explaining what my position really is, and why it was that I was led to sign an apology containing some statements which certainly I demurred very much to. It would perhaps have been better had I acted in some other way. I beg to point out that it is perfectly well known to me that those now acting in opposition to me are most anxious that such a tornado should be raised that it would be rendered difficult or impossible for me to address you. I am sure if you knew all the circumstances involved in this unfortunate matter I should have a considerable amount of sympathy. I should hope that you will not play in the hands of others to render it impossible for me to continue to do those duties which, of course, I am anxious to do in order to help you as much as I can. The time will come, I have no doubt, when all these facts of the case are known. Until that time I hope you will suspend your judgment."

EDINBURGH UNIVERSITY.

The Vacant Rectorship.—The Principal of Edinburgh University, after consultation with the Senatus Academicus, has come to the conclusion that the vacancy in the Rectorship caused by the lamented death of Lord Iddesleigh cannot legally be filled up till November next. A proposal was on foot to request His Royal Highness the Prince of Wales to accept the office, and Liberals and Conservatives were unanimous in the selection. It was thought that it would be a pleasing academic recognition of Her Majesty's Jubilee. Sir Francis Knollys has, however, sent the following message in advance:—"If such an honour were proposed to the Prince of Wales, though he would naturally feel highly flattered, he fears it would be difficult for him to accept it."

The late Lord Rector.—On receiving intelligence of the death of the Earl of Iddesleigh, the University Court adopted the following minute:—The Court desire to record their great sorrow that since their last meeting the sudden death of the Earl of Iddesleigh has deprived the University of his valuable services as Lord Rector, and this Court of its head. The Court, with the fresh recollection of his distinguished talents and his high character, join in the national lament over his loss. Alike at the Tercentenary celebration and during his whole connection with the University, Lord Iddesleigh was ever ready to further its interests, and to identify himself with the students both in their studies and in their recreations. His death, therefore, is deeply felt, and his memory will be long affectionately cherished by all connected with this University. The Court desire that a copy of this minute shall be sent, with this expression of their respectful sympathy, to the Countess of Iddesleigh and the members of the family of the late Earl.

Students' Representative Council.—The elections in connection with the Students' Representative Council, which has become an important element in Edinburgh University life, are in progress.

University Examiners.—The Court has appointed the following gentlemen to be additional Examiners in Medicine, as follows:—Dr. C. D. F. Phillips, London, in Materia Medica; Dr. D. Noël Paton, Edinburgh, in Physiology; Dr. G. Sims Woodhead, Edinburgh, in Pathology; Mr. W. Watson Cheyne, M.B., F.R.C.S., in Surgery; Dr. J. O. Affleck, Edinburgh, in Clinical Medicine. The additional Examiners in the other departments of Medicine were reappointed. The Court further authorised the opening of a class of Practical Botany in the winter session, to be conducted by the Assistant to the Professor, with his superintendence, the laboratory to be open daily, microscopes and re-agents being supplied by the Professor. The fee was fixed at £3 3s. The Court resolved to recognise Mr. Alexander Wood, teacher of Practical Materia Medica, Edinburgh, and Dr. Bruce, Lecturer on Pathology, Edinburgh, as teachers whose courses qualify for University graduation.

The Endowment Association.—The annual general meeting of the Association for the Better Endowment of Edinburgh University was held last Thursday, under the presidency of the Lord Provost. It was reported that four more competition bursaries had been arranged for. The Association had done good work, but the public required to be further stimulated, in order that the annual subscription list might remain sufficiently high. The Lord Provost announced the gratifying fact that the number of students attending the University continues to increase. The announcement of the early introduction of an Universities (Scotland) Bill was hailed with pleasure.

The Southern Counties Asylum Charges of the ex-Medical Assistant.—In the month of August last there appeared in the Glasgow newspapers copious extracts from correspondence published by Dr. Lennox, formerly Medical Assistant to the Southern Counties Asylum. From the correspondence it appeared that Dr. Lennox was appointed Medical Assistant on the nomination of Dr. Rutherford, at the end of 1885; that he occupied the position for about seven months, and enjoyed the entire confidence of Dr. Rutherford, the Superintendent; that on the 11th of June 1886, he wrote a long letter to Sir Alexander Jardine, chairman of the directors, to the Secretary of State for Scotland and the Secretary of the Board of Lunacy for Scotland, charging Dr. Rutherford with subversion of order in the house, and, also making grave charges as to the inferior quality and deficient quantity of the food supplies; that on the 18th June he was suspended by Dr. Rutherford, and on the 23rd dismissed by the directors; that an inquiry into his charges was commenced by the Board of Lunacy in Edinburgh in July; that he was allowed to appear by counsel at the inquiry. The Board of Lunacy and the Commissioners have now both issued their reports completely exonerating the Medical Superintendent, and setting forth that the conduct of Dr. Lennox, the Assistant, was subversive of discipline.

Ayr.—The Hospital.—Mr. Douglas Baird, Wellington Square, Ayr, has, it is stated, undertaken to defray the expense which the directors find will have to be incurred in the improvement of the drainage and other sanitary arrangements of the hospital, and the more satisfactory heating of the infectious wards.

Proposed Medical School for Dundee.—We have kept our readers *au courant* with the aspirations of certain influential authorities in Scotland to give a medical school to Dundee. These have now assumed a more definite shape, and "a proposal for a new medical school" to commemorate the Queen's Jubilee has been issued. In the introduction it is stated that "it has long been felt in Dundee that, with the Royal Infirmary on the one hand, and the facilities for graduation at St. Andrews on the other, the materials already exist for laying the foundation of a medical school." The movement was formally inaugurated by Prof. Gairdner, of Glasgow, in 1885. Subsequently Sir Andrew Clark, M.D., of London, in passing through Dundee, took the opportunity of urging in the strongest terms the foundation of a complete medical school as a duty which Dundee owed to herself. Since then, as our readers are aware, the whole subject has been much discussed, and public opinion in regard to it has been rapidly advancing.

Factory Appointments in Glasgow.—The appointment held by the late Dr. Ebenezer Watson in connection with the factories on the south side of Glasgow has been divided between Dr. A. K. Irvine, of Newton Terrace, and Dr. Brown, Belhaven House, Pollokshields.

Literature

RECENT WORKS ON THE NERVOUS SYSTEM.

I.—*A Manual of Diseases of the Nervous System.* Vol. I. By W. R. Gowers, M.D. London: J. & A. Churchill. 1886.

The present volume deals with Diseases of the Spinal Cord and Nerves, while Vol. II, which treats of Brain and General Nervous Diseases is in the press. What we have presently under review, is a copious work of 460 pages, illustrated profusely, and with considerable detail and variety. The principal features of nervous disease receive unstinted representation, and small and isolated paralyses are severally brought into focus, and accorded a careful notice. We think it right to direct particular attention to the liberal and very effective manner in which the book is illustrated, for the illustrations, which are in a rare degree, fresh and original, give the work a high distinction and value. At the outset the Author makes some very obvious remarks on the broad classification of nervous diseases into functional and organic, which has so long obtained. This, as he very properly remarks, is a faulty conception of what these terms embrace, for the term organic, is relative and elastic, in proportion as methods of investigation improve and identify more and more the minutiæ of disease. Dr. Gowers distinguishes a class of "Nutritional Diseases" from those that consist in a mere derangement of function, but here a difficulty obscures definition, nutrition is a function, and function is dependent on nutrition. This reservation has not been lost sight of in treating of the subject. Organic disease is considered for purposes of classification in respect of its visibility by naked eye, and microscopic methods; those which are only visible macroscopically when in large amount are classed with microscopic disease as structural, while coarse organic lesions come under the group of Organic Disease proper. The classification, therefore, is thus briefly stated:—

I. Organic Disease (of course organic disease). II. Structural Disease. III. Nutritional Disease. IV. Functional Disease. This classification is not pursued further, probably in view of its immature development; but it is worth ripening and experimenting with afterwards. Meanwhile, the diseases are treated in relation to site, and the first volume which for a brief space is occupied with General Symptomatology discusses in Part II Diseases of the Nerves; and in Part III, Diseases of the Spinal Cord. The method of arrangement is very satisfactory, there is no redundancy of expression, and the work throughout, is marked by originalty of design, clearness of exposition, and a large and practical grasp of the subject. To estimate it further, would be mere iteration. We commend it as a valuable treasure of neurological knowledge.

II.—*Paralysis, Cerebral, Bulbar and Spinal.* By H. Charlton Bastian, M D. London: H. K. Lewis. 1886.

Dr. Bastian's treatise is essentially a manual of diagnosis, and his style is pointed, even abrupt it may be considered; because of its directness and brevity of expression it involves conclusions not always at first sight obvious, and because of its dogmatism, it allows too little free play of criticism. The faults are rather in the style than in the matter, and for students they may be regarded as virtues; for dogmatism and directness especially, when teaching diagnosis are qualities which do not seem to thrive in an atmosphere of scientific enlightenment. The author does not accord a high place to experimental physiology, he admits that "experiments often sharpen the observation of the physician, and may open his eyes to signs or symptoms previously unnoticed, but they do little more." He is out and out a clinicist and pathologist. His method of arrangement, and his views on diagnosis, while sometimes original, are usually eminently practical. He scores a point in his observation that "from the point of view of symptomatology, the region affected is of much greater significance than the nature of the lesion." He has a masterly grip of his subject, and keeping the goal of diagnosis steadily in view, carefully and effectively arrays his forces, and leads up to it on clear and definite lines. The work is treated in four sections. I. Paralyses of Encephalic Origin. II. Paralyses of Bulbar Origin. III. Paralyses due to lesions of the Cranial Nerves; and IV. Paralyses of Spinal Origin. Clinical and pathological considerations determine the particular disposition of each section, and the method of study involved is natural and practical, rather than uniform and artificial. Varieties of printers' type are employed to give distinction and emphasis, but they are not happily selected, and rather a blot upon the book. It well deserves a place on the bookshelf of the student and practitioner, for it is the rich outcome of experience and is eminently practical.

III.—*Spasm in Chronic Nerve Disease.* By Seymour J. Sharkey, M.B., F.R.C.P. London: J. & A. Churchill. 1886.

Mr. Sharkey founded the Gulstonian lectures of 1886 on this subject, and has treated it with considerable detail and variety of interest. A large selection of brief, but intelligible clinical records, bearing more or less upon the subject, find a place in the lectures, and give them enhanced value, and many good and appropriate illustrations are interleaved. The subject is considered under (1) Spasm in connection with cerebral motor mechanisms. (2) In connection with spinal mechanisms. (3) Functional spasm. There is, perhaps unnecessary reference to, and reproduction of, facts already well established and widely known. The motor area of the cortex for example is here reproduced, as in every fresh book that appears, until it has become the best known of all the cerebral parts. The arrangement of motor fibres in the internal capsule, might have been more fully described, and with the aid of diagrams; for here we are on ground of more recent investigation, and more debatable character. These are objections mentioned by the way, but they are of slight importance in the light of the solid array of clinical and pathological data, which the author has placed in the archives of neurological medicine. The work is valuable, and has opened up comparatively unknown ground. It deserves an enduring place as complementary to the best books on nervous disease.

IV.—*Insanity Curable.* By George Moseley. London: J. & A. Churchill. 1886.

This fascinating title is sure to awaken scepticism; surely, insanity has all along been curable, and surely the grounds of its curability have not been brought to light suddenly in this phenomenal style. The sensational manner of this book's appearance is accentuated, when we further study the title page. "Mental Disorders and Nervous Affections of recent origin, or long standing. Their cause are now successfully treated by a new Especial Method." To take such liberties with the Queen's English, is bad enough, but to arrogate to oneself at this time of day, all the virtues implied in such a title is absurd. It is so utterly at variance with the usual modest and sensible methods of medical writers, as to savour of advertisement. The body of the work bears out one's disappointment with the author, who quotes from others, and strings together paragraphs which are neither clever, original, or applicable to the subject. He implies much, talks with an assumption of authority; but never descends from the clouds of omniscience, and we search in vain for his wonderful nostrum. It is a pity that such books should appear in the name of any member of our profession. What he knows, he has picked up from the writings of others. His ignorance of the subject is the most striking feature of a book which being intended as a popular guide, is all the more objectionable.

ANATOMY AND PHYSIOLOGY IN CHARACTER. (a)

This is a delightful book, witty and wise, clever in exposition, charming in style, readable and original. In the mass, its doctrines are not new, but they are displayed in such a garb as to suggest originality, as well as novelty, and in detail, the thesis is made out with many dashes of originality, a wealth of quotation and research, a rare force of argument and elegance of diction. The work is, the author says, the result of several years of close observation; and he apologises for the use of one or two clumsy epithets; this apology might be spared, for they are so rare exceptions as to mark out by contradistinction, his choice and happy literary faculty. The first chapter treats of Physiology in Human Affairs, describes mankind as a collection of nerve units, and life as a succession of nerve incidents. The author believes implicitly in heredity, puts brain first, and circumstances a long way after. He pertinently asks,

---

(a) "Anatomy and Physiology in Character." By Furneaux Jordan, F.R.C.S. London: Kegan Paul, Trench & Co.

"Could any possible combination or succession of circumstances have enabled the third George to write Hamlet? Could any conceivable surroundings or antecedents have converted Shakspere into an obstinate or feeble witted monarch?" As students of character, he places Carlyle and George Eliot before Mill and Dickens. The second chapter takes up the "Origin and Nature of the Enquiry" and begins with a description of assaulted wives, as the author studied them in hospital. "They differed in some mysterious way from the women who were admitted for purely accidental injuries, they were not old and ugly, but as a rule, young and pretty."

Then follows an anatomical description, embodying shrewd and acute observations. The third chapter, describes the character of the Shrewish Women all round from every point of view. The fourth chapter, the character of the Shrewish Man; and the fifth and sixth chapters, their opposites. The seventh treats of the Anatomy of Shrewish and Non-Shrewish persons. The eighth of the Physiology of Shrewishness; and the book concludes with a note on Shrewishness and Non-Shrewishness in literature. Space forbids our enlarging further Few will accept *in toto* the author's views, many will think them too sweeping; but all will admit, his painstaking faculty and shrewdness. We commend the book as a most enjoyable, intellectual treat tor all educated classes, and for none more so, than for the medical profession, a treat rich in character studies, in shrewd observations and comments, and in happy generalisations.

Correspondence.

THE LAPAROTOMY EPIDEMIC.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Dr. Keith knows as well as anyone that success can only come of experience. His own phenomenal success in hysterectomy cannot place that operation in comparison with the minor one of removal of the uterine appendages for bleeding myoma, which is so confidently recommended by Mr. Lawson Tait. The beneficial results may be slower, and the plaudits less loud, but as a matter of safety the latter operation, when practicable, will be preferred by prudent surgeons. In face of the fifty per cent. mortality of Sir Spencer Wells in hysterectomy, we must be content to undergo the sarcasm that we remove the appendages because we dare not remove the uterine tumour. Sometimes these uterine tumours are so embedded in the pelvis that their removal is quite impossible, and they are often more disabling to the patient than when they mount freely into the abdominal cavity. Out of twenty-seven cases in which I have performed this operation only two have died. After one of them, sent to me by Dr. Chisholm, had fully recovered, her husband came to see her and to arrange about taking her home. A few hours after he left she sickened, and in a few more she died. The husband confessed to having given her four ounces of paradise sweetmeats, of which she must have consumed all but an ounce and a half; and at the post-mortem examination, which was conducted by Dr. Davies, we found a perforation of the duodenum, and the whole of the peel and many of the pips of an orange, as well as a number of grape skins, scattered freely about her peritoneal cavity. The second one, sent to me by Dr. Barnardo, died of septicæmia on the fourth day. The pathologist of the Royal Infirmary, who performed the autopsy, could find no cause for the collection of septic fluid except that the kidneys were fatty. I only knew after the operation had been performed that my colleague had had an infective patient with pyosalpinx in hospital for five weeks with a constant purulent discharge. That this discharge was infective was shown by the illness of the nurse in attendance, whose temperature suddenly rose to 103°, and by the death of Dr. Burton's patient, without operation, though not without consultation, two days after mine.

Neither of these cases proves the operation to be dangerous, and I, for one, am fully convinced of its utility in suitable cases. Patients with pyosalpinx, hæmatocele, and so on, are under a different category. Assuming that the operator is familiar with the manipulative details and management of these cases, the mortality chiefly depends upon the lateness of the stage at which the risk is undertaken. It is scarcely possible to say dogmatically of any case that it is too late, for remarkable recoveries after advanced peritonitis are common, and the question must be left to the patient and her friends. The outcry seems to be chiefly directed against the operation for chronic ovaritis and salpingitis with peritoneal adhesions, but Dr. Keith himself appears to have been driven to it, with satisfactory results as regards relief from pain. Still there is little immediate danger to life in these latter conditions, and if any one will formulate a rational method of relief which does not involve surgery I shall be delighted to try it, for I know none. Rest was thought of before 1887, and I believe regulated exercise, with rest only during the menstrual period, to be far more beneficial. Gin and morphia and chlorodyne, so far as I am aware, are the medicaments chiefly relied upon by those who denounce operation, but we want something less harmful and more useful than these. Dr. Burton informs you that I had nearly twice as many patients under my charge in 1885 as he and Dr. Lupton together, and that my percentage of removals of uterine appendages was greater than theirs. This is true, but I never stated anything to the contrary. He has inadvertently under-estimated his number of "castrations," and has altogether omitted his unfinished operations for pyosalpinx, which are entered as "pelvic abscess—exploratory incision."

Yours, &c.,

Liverpool, Jan. 30th. Francis Imlach.

HYDROPHOBIA OR TETANUS?

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The "case of hydrophobia" at St. Bartholomew's Hospital, under the care of Dr. Southey, reported in your current issue, has aroused deeply in my mind the inquiry, whether or not it was a case of tetanus following a wound. In reading this report, my mind reverted to the "inquiry into the reported poisonous nature of the arrows of the South Sea Islanders, in relation to the occurrence of three fatal cases of tetanus, after wounds by them on board H.M. ship *Pearl* in 1875, by Staff-Surgeon A. B. Messer, M.D., R.N., ("Report on the Health of the Navy, 1875." Appendix, p. 149).

The symptoms in the cases of arrow wounds in the *Pearl*, were like to those of Dr. Southey's case. Dr. Messer writes (*op. cit.*, pp. 157-8): ". . . On the day of injury there were no indications whatever of poisoning or other constitutional disturbance. . . . Beyond a little anorexia in one, and some pain and swelling about the wounds of other two, no decided signs of mischief appeared, either in the wounds, or constitutionally, in any of the others till the fifth day. Then want of sleep and uneasiness about the wounds began in one case. On the following day spasms began, in this case to radiate from the wound, and the disease might be considered established. At this time the same ominous want of sleep, and with pain and spasm near the wound, appeared in the second case. In the third case, stiffness of the jaw and pain in the wound were the signs which appeared first on the seventh day." ". . . Mr. Morgan relates cases where the spasms commenced in the muscles of the parts injured. This took place in two out of the three cases, and in them it then spread to most of the voluntary muscles. Severe spasms of the diaphragm were present towards the end in a great or less degree in all." "Death took place in the spasms writes in two, and by exhaustion in the other case." Dr. Messer (*op. cit.*, p. 152) of a general tendency towards tetanic writes symptoms:—"Other slighter cases of nervous or hysterical tetanus appeared at this time, and showed how powerful was the mental influence in inducing a nervous state closely allied to the real disease, and which we think goes far in support of the theory, that fear and mental emotion are predisposing causes of tetanus, if not actual producers of it, when they are associated with a wound under certain conditions of climate and hygiene."

There seems to be a natural tendency to an exalted and extreme action of those nerve centres and nerves, which are involved in tetanus. This disturbed nerve-energy may, it seems, evolve without wounds, certainly without "poisons;" but in the main, the great and fatal disturbance of normal tension or molecular nerve-action, is started on its course by the changes which a wound involves.

As in other diseases, or deviations of the system's normal rates, the tendency to tetanus, though greatest in the tropics, yet the tendency overlaps amongst the inhabitants of higher latitudes.

It has always appeared to me that the *de novo* evolution or autogeny in some instances, and the great tendency towards the evolution of tetanus in the tropics, from simple and slight wounds, have a great bearing on the natural history of cases of reputed hydrophobia. On the other hand, we have to remember that tetanic spasms in the frog will follow the hypodermic injection of strychnia, such spasms recurring for a period of many months, as the result of one such injection. (Dr. G. Harley in *Med. Times and Gaz*,, December 3rd, 1881, p. 653.)

Hypothetically granting that hydrophobia has followed and resulted from the molecular energies, or states, which belong to the salivary secretions of some animals at certain times, we are not by such an hypothesis, precluded from, at the same time, holding the other hypothesis, viz., that of the sometimes auto-genesis of tetanus, for cases of tetanus, undistinguishable from hydrophobia, have often been seen to follow simple wounds.

In this study, the phenomena presented by Nature, are broader, and have wider corelations, than either hypothesis will embrace.

A theory which shall embrace the whole of the phenomena will probably find its base in the facts, of the vast differences in power and influence on the vital being, of organic bodies, of the carbon and nitrogen compound—radical groups, of nearly isomeric composition, or of polymeric modifications.

It is admitted to be very important in Method, that we seek to corelate our cases and single facts, with the wide groups to which they are in Nature allied, and this consideration must be my excuse for the hypothetical and tentative remarks I have made.

Yours, &c.,

January 28th, 1887. M.D. EDIN.

◆

THE ACADEMY OF MEDICINE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I shall feel obliged by your inserting the following:—On December the 16th, 1886, I wrote asking the General Council of the Academy of Medicine in Ireland at what special or sectional meeting in January I could read a paper or an introduction to a discussion on important changes required in the governing and examining boards of the medical and surgical corporations in the teaching at the Dublin medical schools and hospitals, and in the treatment of the sick poor in our hospitals. On January the 12th, 1887, I received a reply from the President and Council of the Academy saying that the subject of my paper would properly come before the Sub-Section of State Medicine, and, that as the subject is an unusual one, it will be necessary to submit the paper before reading it to the Committee of the Sub-Section. I sent a reply refusing to submit my paper to supervision before reading it, as I could find no rule among the regulations of the Academy to that effect. On January the 14th I was informed that under a provision in rule 19, "any regulation of the Council shall have the force of a law until submitted to the next general meeting."

This is, I believe, the first occasion on which the Council of the Academy of Medicine (which is principally composed of Fellows and persons connected with the corporate and other institutes, whose imperfections I wished to have discussed) have arrogated to themselves such authority. It appears to me necessary that the Council of the Academy of Medicine in Ireland should, if possible, be restrained from exercising unjust and illiberal restrictions, and encroaching on individual rights and privileges, unless they wish to make it like the narrow-minded and self-interested medical and surgical corporations of the city, which have done less to advance the interests of medicine and surgery than any similar institutions in Great Britain.

I am, &c.,

J. P. DOYLE,
Physician and Surgeon.

69 Lower Mount Street, Dublin,
January 19, 1887.

VACCINIA AND VARIOLA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is somewhat curious to note that the question as to whether vaccinia is or is not modified variola is still debated. For instance, in one of the medical journals recently, Dr. Fleming has put forth the view that they have not been shown to be related. For my part, I have long ago made up my mind that vaccinia is mitigated variola, having had the advantage of personally conversing on the subject with the late Mr. Ceely of Aylesbury, with Mr. Badcock, and also with Dr. Green of Birmingham. All of these most able authorities themselves inoculated small-pox on cows, and saw well-marked vaccine vesicles arise, which they used to carry on vaccination with, and they were very successful in protecting their patients from possible contagion of small-pox. Some time since I received a letter from M. Pasteur, in which that gentleman expressed his weighty opinion that vaccinia was variola mitigated by its passage through the bovine species. I see also that Dr. Pavy, in his Harveian Oration of 1886, thus expresses himself (p. 49) "It may now be regarded as an accepted conclusion that vaccine lymph is the virus of small-pox, modified by transmission through the cow." I cannot help thinking that Dr. Fleming would do the State a great service if he would recommence, as I proposed at the Medical Society of London (Jenner's Society) some years ago, a series of experiments in the inoculation of the dovine species with small-pox virus, and thus let the question be settled for all future generations.

I am, Sir, your obedient servant,

Jan. 20th, 1887. M. D.

Obituary.

DEATH has been busy in the ranks of our profession in Ireland within the past week. Chief amongst the losses sustained has been the demise of Dr. Henry Kennedy, of Dublin, who was well known as one of the most diligent students and untiring readers in the profession, as well as a genial and upright gentleman. He took the degrees in Arts and Medicine of Dublin University in 1839, and became a Fellow of the College of Physician ten years later. He served as Physician to the House of Industry, and Sir Patrick Dun's Hospitals, and was well known as a clinical teacher. His writings on scarlatina, on fatty heart, and on the paralytic affections of childhood secured for him the reputation of a careful observer and accurate writer. His funeral was attended by the President and Fellows of the College of Physicians in official form. By his death, the physiciancy of the Whitworth Hospital, at Drumcondra, and of Simpson's Hospital, are rendered vacant.

Another noteworthy event is the death of Dr. Morgan O'Connell, of Kilmallock, one of the fathers of the profession in Ireland. Dr. O'Connell obtained his first qualification from the London College as far back as 1835, and became a Fellow of the Irish College of Surgeons in 1845. In early life he served in the British army as a surgeon. In 1830 he joined the British Legion, and proceeded to suppress the rebellion in Spain to dethrone Queen Isabella. He served in several engagements in Spain, and was presented by Queen Isabella with the gold medal and clasp of the Legion of Honour, bearing the inscription "Spain intends to show her gratitude." King Ferdinand conferred upon him the honour of Knight of the Order of St. Ferdinand. Dr. O'Connell left the army shortly after his return home from Spain, and settled down as medical practitioner in the town of Kilmallock. He had been medical officer of the workhouse and dispensary for only one year less than half a century, but was compelled by the deficiency of the law and the niggardliness of the guardians to continue in office long beyond his eightieth year of age.

Dr. Hanan, of Tallow, in the county Waterford, also died last week. He was even the senior of Dr. O'Connell, having qualified as L.R.C.S.I. in the year 1828, nearly sixty years ago. He, nevertheless, held the office of dispensary doctor up to his death, not daring to resign, as he knew that his guardians would refuse him the needful pension.

◆

DR. BRYANS, of Pettigo, has been called to the Commission of the Peace for the County Fermanagh.

Medical News and Pass Lists.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

At a meeting of the College held on Thursday last, under the Presidency of Sir Wm. Jenner, Bart., the following business was gone through:—Communications were read from—1. The Royal College of Surgeons, inviting three Fellows to consider the question of the Queen's Jubilee (the President, Treasurer, and Registrar appointed). 2. Dr. Parker, with drugs from Japan, referred to Committee. 3. The Metropolitan Branch of the British Medical Association. 4. Medical Officers of Health.

Dr. Habershon, Sir E. Sieveking, Dr. Blandford, Dr. Sturges, and Dr. Morgan were elected on the Council.

The Council's report was adopted as follows:—The Council has had under its consideration the question referred to it by the College, viz., whether or not the "Certificate in Hygiene" granted by the College should have its title altered. Having consulted the recent Act of Parliament which makes a diploma registrable by the Medical Council, and having considered the title adopted generally by other bodies granting a testimonial of proficiency on this subject, the Council recommends that in future the title "Certificate in Hygiene" be changed to "Diploma in Public Health," and that, inasmuch as the two Colleges are now acting conjointly for examination purposes, except in the case of their honorary distinctions, that is to say, the Fellowship of either College, and the Membership of the College of Physicians, the Council recommends that the College of Surgeons be invited to associate their body with this College in the granting of the "Diploma of Public Health."

The following report of the Examiners was adopted:—The Examiners for the Licence beg leave to present their annual report to the College:—During the past year 465 candidates have presented themselves at the First Examination. Of these, 293 passed, and 172, or 36·9 per cent. were referred. At the Second Examination there have been 14 candidates, 9 of whom failed to pass. At the Third or Final Examination, 534 candidates were examined, and of these 340 were approved, and 194, or 36·3 per cent., were referred for further study. As regards the results of the examination conducted by the Conjoint Examining Board, the details of these, as also of those for the Licence of the College, have been printed in a tabular form, and are now laid before the College.

The quarterly report of the Finance Committee was also adopted.

HOUSE OF INDUSTRY HOSPITALS.

Dr. Thomas Donnelly has been appointed by the Board of Governors of the House of Industry Hospitals to be Assistant Physician of that institution, subject to the sanction of the North Dublin Guardians and of the Local Government Board being obtained to a change in the hour of his official duties as Dispensary Medical Officer, which will enable him to discharge the duty at the Hospitals. Dr. Donnelly is an M.D. of Dub. Univ., a Fellow of the College of Surgeons, and graduated as Senior Moderator in Experimental Physics.

While Dr. Donnelly's attainments fully justify his appointment by the Board of Governors, we feel, nevertheless, bound to express the opinion that it is very undesirable that an hospital physiciancy or surgeoncy shall be held along with a dispensary appointment.

An active and ambitious young man may be anxious to undertake the double office with full intention of doing the double duty, but it is scarcely possible that either office can be done justice to, and it has already been notorious that in Dublin the arrangement has worked badly. We should be sorry to stand in the way of any one's legitimate advancement, but we object to pluralities, and it is our duty to point out the objections thereto.

Medico-Psychological Association.—The next quarterly meeting of this Association will be held at Bethlem Hospital, St. George's Road, S.E., on Wednesday, 23rd February, at 4 o'clock, when it is proposed to discuss the question "Whether there is ever sufficient reason for the use of strong clothing and side-arm dresses." Dr. Percy Smith will afterwards read a communication on "The Results of an Epidemic of Typhoid Fever in the Insane." After the election of new members, the Association will dine together at the Holborn Restaurant at 7 p.m. Members intending to dine should notify the same to Dr. Paul, The Terrace, Camberwell.

The Stanley Expedition to Central Africa.—Before the intrepid explorer left these shores last week we were shown his medical equipment, which is very considerable. The medicine chests, which are unique in several particulars, were devised and manufactured by Messrs. Burroughs, Wellcome, & Co., of London, with the aid of Mr. Stanley's valuable suggestions. Some of them are of raw hide some of teak-wood, and others of iron. The average weight is 36 lbs., which is about half the usual load carried by an African porter. They can be easily carried on a long march by a white man by slinging it over one shoulder with the accompanying leather strap. In addition to the ordinary medicines, such as castor oil, turpentine, magnes. sulph., soda sulph., &c., there are many drugs in the soluble compressed form, which reduces quinine to about one quarter its ordinary bulk. These tablets dissolve in a glass of cold water in three minutes, and are even more soluble in the mouth or stomach.

Royal College of Physicians of London.—The following candidates having passed the necessary examinations were duly admitted Members of the College on January 27th:—

Maconachie, George A., M.D., Aberd.
Marston, Jeffrey A., M.D. St. And.
Reid, James, M.D. Aberdeen
Smith, Frederick John, M.B. Oxon.

The following were admitted Licentiates:—

Andrews, Archibald George
Ballance, John Des Carrières
Barlow, Charles
Barr, George Arthur
Barton, Edwin Alfred
Belson, George de Veulle
Blenkinsop, Alfred Percy
Bostock, Robert Ashton
Boxall, Frank
Bradbury, Harvey Kimmersley
Brodie, Fredk. Carden
Browne, Edward Granville
Bulstrode, Herbert Timbrell
Butler, Henry John
Calthrop, Lionel Claude
Calvert, John Telfer
Calvert, William Dobree
Clark, Brown
Connolly, Frank Glynn
Cosens, William Burrough
Cox, Alfred Harold Lissant
Crook, Herbert Evelyn
Cross, Robert George
Dalgleish, John William
Debenham, Horace Allen
Downing, William
Downman, Charles Frederick
Drinkwater, Charles
Duncan, Horace
Duncker, William Reinhold
Edye, John Simpson
Evelyn, William Arthur
FitzGerald, Gerald Eustace
Fraser, Paul Wilkes
Furnivall, Bryan
Garrould, Walter Robert
Hall, Herbert Strange
Haslip, George Ernest
Helsham, Hugh Paul
Holloway, Samuel Frederick
Husbands, Harold Wessen
Iredale, Thomas
Jarvis, William Charles
Jeaffreson, John Leslie
Johnson, John George
Joly, Joseph Antoine Maurice
Jones, John Owen
Kitson, Francis Parsons
Knaggs, Francis Henry
Lansdale, William
Loxton, William Arthur
McKague, William Henry
McShane, George
Mann, Harold Edward
Martin, Frederick George
Maxwell, Matthew
Miller, Frederick Richard
Moore, James
Morgan, George Frederick
Morgan, William Vaughan
Mould, William Thomas
Moxham, Marcus Camplin
Nihill, John Edward
Ord, George William
Pedley, George Aston
Peeke, Harold Samuel
Pepler, William Herbert
Pinniger, Charles Lever
Powell, Edgar Elkins
Quiller, Charles Turner
Roalfe-Cox, Walter John
Rosenau, Albert
Sharman, John Schütze
Stott, Hugh
Strickland, Percy Charles
Thane, Edgar Herbert
Thompson, Stephen Robert
Trow, Charles
Tweed, Edward Reginald
Vidler, Albert Edward
Wale, George
Walker, Alfred William
Wheeler, Humphry John
Wilbe, Richard Haydock Wiffin
Wilson, William
Wreford, John

Royal College of Surgeons in Ireland.—The following have been admitted Fellows of the College:—

Ashbury, Alfred, A.M.D.
McMullen, James, A.M.D.

Vital Statistics.—The deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 22·8 per 1,000 of their population, and were—Birkenhead 18, Birmingham 23, Blackburn 24, Bolton 20, Bradford 20, Brighton 15, Bristol 25, Cardiff 24, Derby 15, Dublin 32, Edinburgh 23, Glasgow 27, Halifax 26, Huddersfield 24, Hull 21, Leeds 28, Leicester 19, Liverpool 26, London 21, Manchester 30, Newcastle-on-Tyne 26, Norwich 15, Nottingham 22, Oldham 19, Plymouth 33, Portsmouth 23, Preston 32, Salford 19, Sheffield 19, Sunderland 22, Wolverhampton 25. The highest annual death-rates in these towns last week were—From measles, 1·3 in Newcastle-upon-Tyne and in Wolverhampton, 1·4 in Liverpool, 3·0 in Leeds, and 4·1 in Huddersfield; from whooping-cough, 1·4 in Leeds, 1·5 in Manchester, and 1·7 in Norwich and in Huddersfield; from scarlet fever, 1·1 in Norwich, 1·8 in Sheffield, and 2·0 in Plymouth; and from "fever," 1·0 in Cardiff. The 32 deaths from diphtheria included 13 in London, 8 in Glasgow, and 2 each in Portsmouth, Liverpool, Manchester, and Preston.

Notices to Correspondents, Short Letters, &c.

DR. W. H. P.—Thanks for local journal received. The practice which was so stoutly objected to has since been adopted and carried out with great vigour by the contemporary named. The same may be said of several innovations first originated by us, We do not object, but the copies might be acknowledged with some show of etiquette.

MR. W. E. GEDDES.—Our remarks were intended solely to apply to extra-professional advertising such as is unfortunately adopted by some firms in the lay press. Our caution was intended for and is applicable in this connection only; it had no reference to your extract, which we know to be a very excellent therapeutic agent.

A CORRESPONDENT has called our attention to an advertisement for certain pills which is posted up in the windows of a shop in a street leading off the Strand. There are two categories of pills—the A and the B pills, the first for *un*married and the second for married women. The salient point lies in the caution which follows:—N.B. Unmarried women are cautioned against taking the Pills B, as they are liable to cause miscarriage. The object is tolerably clear, but so specious is the wording that it is not easy to see how the law could take cognisance of the intention. We shall, nevertheless, call the attention of the authorities to the *affiche* in question.

COSMOGONIST.—The late Frank Buckland ascribed the puckered "crow's foot" features of the peasantry near Peterhead to the bleak climate of that place, and to the fact that they are obliged to pucker up their eyes to keep out the snow in winter and the dust in summer.

INQUIRER.—Yes; we believe that the herring is one of the most prolific of salt-water fishes. The annual take of them is prodigious. About a million of barrels, representing 800,000,000 fish, are taken annually in Scotland. Probably the same "take" is made on the coasts of Ireland, France, Holland, and Norway, and this being so, some 2,400,000,000 herring must be annually taken by these four nations. Cod and ling, gulls and gannets, eat up as many more, and from this you can only come to the conclusion that your surmise is not far out. The late Frank Buckland believed that "a hundred million soles are yearly sold in the London market alone."

A NOVEL CAUSE FOR ACTION.

IN our last we referred to an action then pending against the proprietors of the Holborn Restaurant for damage said to have been sustained by a Mr. Brett, through swallowing a needle and thread dished up with spinach. The trial, has now concluded, and while sympathising with the gentleman referred to, in the mishap that befell him, we are glad to find the proprietors of this establishment were able to show that the accident could not have happened as the plaintiff thought, and the evidence adduced was conclusive to both judge and jury.

PROFESSOR MAPOTHER.—We will make the necessary correction when the proceedings of the society come to hand.

A DOUBTER.—We think the noble lord in question was quite justified in going at once to Paris, after being bitten last week by a fox, and placing himself under Pasteur's care. Though, as we have before contended, it is too early yet to pronounce definitely on Pasteur's discovery, yet there has been sufficient evidence of its value in some cases as to warrant any one bitten to resort to treatment. Had this remedy been available in the days of old, when one of the Dukes of Richmond was at the time Governor-General of Canada, it is possible his life might have been saved by it. He, too, was bitten by a tame vixen fox, and died soon afterwards, in horrible agony, of this bite.

PHYSIOLOGIST.—The relative weight of the brain does not necessarily suggest greater sagacity in its owner. It merely implies greater cultivation of it on his part, and it is a mistake to say that man takes in either case the highest place. For, although the weight of the brain of the whale is only 1-3300, that of the elephant 1-500, of the dog 1-250, man is surpassed by the song birds and some other creatures. The weight of the former's brain reaches 1-27; it reaches respectively 1-12 and 1-27 in the titmouse and the sparrow, and it amounts in some American apes to as much as 1-28 to 1-18 of the weight of the body.

F.R.C.S.—Mr. Fitzroy Benham, of West Kensington, is, we understand, to be the originator of the "Jubilee Hospital Scheme," referred to in our last issue. Whoever concocted the advertisement of it that appeared in a contemporary ought to bring an action against the pedagogue who taught !! him grammar. The same advertisement was sent to this journal, but was corrected by our publisher before insertion.

SIR SPENCER WELLS, Bart., Sir Wm. MacCormac, Dr. Pavy, Dr. Langdon Down, Dr. Harley, Dr. Routh, Dr. Sansom, Mr. Lane, and Mr. Henry Lee are thanked for their communications.

A HATER OF SHAMS will find a reply to his query under the signature of another correspondent, "F.R.C.S.," who asks the same question. We cannot revert to the subject at present, having fully expressed our views so recently as January 19th, which further inquiries have failed to modify.

AN EDINBURGH STUDENT is thanked for two Edinburgh newspapers containing references to "The Professorial Squabble." Our authorised Edinburgh correspondent had, however, anticipated his note.

◆

Meetings of the Societies.

WEDNESDAY, FEBRUARY 2ND.

OBSTETRICAL SOCIETY OF LONDON.—At 8 p.m., Specimens will be shown. Dr. Gibbons: Case of Unilateral Galactorrhœa. Annual Meeting—Election of Officers and Council. The President (Dr. Potter) will deliver the Annual Address.

SOCIETY OF ARTS.—At 8 p.m., Dr. Alfred Carpenter: Sewage Irrigation.

THURSDAY, FEBRUARY 3RD.

ACADEMY OF MEDICINE IN IRELAND.—At 8.30 p.m., the Sub Section of State Medicine will meet in the College of Physicians. Business:—Address by the Chairman (Dr. J. W. Moore): The Present and the Future of State Medicine. Sir. C. A. Cameron, F.R.C.S.: On the Clearance of an Unhealthy Area without Expense to the Ratepayers.—The Obstetrical Section will meet on Friday at the College of Physicians.

ROYAL INSTITUTION OF GREAT BRITAIN.—At 3 p.m., Prof. A. W. Rücker: Molecular Forces.

HARVEIAN SOCIETY OF LONDON.—At 8.30 p.m., Mr. G. Buckston Browne: The Position and the Value of the Operation of Internal Urethrotomy. Sir W. MacCormac: The Supra-Pubic Operation in its application to Stone in Children.

FRIDAY, FEBRUARY 4TH.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—At 8 p.m., Living Specimens:—Mr. Keetley: (1) A Case of Arterio-venous Aneurysm of Cavernous Sinus (?) after Treatment by Compression; (2) A Case of Cholecystotomy. Card Specimens:—Mr. H. Percy Dunn: (1) A Large Intussusception from a Child; (2) Tuberculosis of the Spleen from a Child of three months; (3) Extensive Rupture of the Duodenum following a Kick from a Horse. Papers:—Dr. Thudichum: On the Nature and Operative Treatment of Hypertrophies and Tumours of the Nasal and Pharyngeal Cavity. Dr. Campbell Pope (for Dr. Suckling): A Case of Acute Multiple Neuritis following Diphtheria, and one of Unilateral Progressive Facial Atrophy.

MONDAY, FEBRUARY 7TH.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—At 8 p.m., Casual Communications by Messrs. A. S. Underwood, E. G. Betts, Storer Bennett, C. D. Davis, J. Ackery, W. H. Coffin, L. Matheson, C. Robbins and Willoughby Weiss. President's Inaugural Address.

Vacancies.

St. Bartholomew's Hospital.—Assistant Physician. Honorary. Applications to the Clerk on or before Tuesday, the 8th February.

Hull and Sculcoates Dispensary.—House-Surgeon. Salary, £150 per annum, with house (unfurnished), coals, and gas. Written applications, with testimonials, &c., must be forwarded on or before February 1st to the Honorary Secretary.

Norfolk and Norwich Hospital, Norwich.—Assistant to House-Surgeon. Board, lodging, and washing provided, but no salary. Applications, with testimonials, to be sent in to the House-Surgeon, on or before Feb. 3rd.

Eye, Ear, and Throat Hospital for Shropshire and Wales, Shrewsbury. —Surgeon. Honorarium, £150 per annum for three years Applications and testimonials to be sent in on or before Feb. 8th to the Secretary.

Liverpool Northern Hospital.—Assistant House-Surgeon. Salary, £70 per annum, with residence and maintenance in the house. Applications, with testimonials, to be addressed to the Chairman of the Committee not later than Feb. 7th.

Appointments

DRANE, E., L.R.C.P., M.R.C.S., House-Surgeon to the Royal Berks Hospital.

GAYE, H. S., M.D St.And., M.R.C.S., Consulting-Surgeon to the Newton Cottage Hospital and Dispensary.

GREENE, G. E. J., L.R.C S.I., L.K.Q.C.P.I., Medical Officer for Ferns Dispensary, Enniscorthy Union.

LITTLE, A. N., M.R.C.S., L.S.A., Third Assistant Medical Officer to the Worcester County and City Lunatic Asylum.

MORRIS, E., M.R.C.S., L.S.A., Medical Officer for the Fernhurst District of the Midhurst Union.

SHAW, L. E., M.D., M.R.C P., Medical Registrar and Demonstrator of Practical Medicine to Guy's Hospital.

SOUTHERN, J, M.R C.S., L.S.A., Medical Officer for the Ludlow District of the Ludlow Union.

TREDINNICK, E., M.R.C.S., L.R.C.P.Ed., Medical Officer for the Stokesay District of the Ludlow Union.

WATSON, H. O., L.R.C.P.Ed., L.F.P S.Glas., Medical Officer for the Clee Hill District of the Ludlow Union.

Births.

BALDING.—Jan. 24, at Dane House, St. Albans, the widow of Mortimer Balding, M.D. Cantab. (who died on Nov. 23rd, 1886), of a son.

JOBSON.—Jan. 26, at Keillour House, Perth, the wife of Brigade-Surgeon Jobson, M.D., of a son.

O'CONNOR.—Jan 22, at Clane, county Kildare, the wife of Dr. C. J. O'Connor, of a son.

Marriages.

JESSOP—ROGERS.—Jan. 27, at St. Pancras Parish Church, Edward Jessop, M.R.C.S., L.R.C.P., of Bridgegate, Retford, to Ada, youngest daughter of Thomas Arnold Rogers, of 23 Endsleigh Street, London, W.C.

SIMON—WILLANS.—Jan. 26, at Christ Church, Lancaster Gate, Robert M. Simon, M.B., M.R.C.P., of Edgbaston, Birmingham, to Emily Maud, younger daughter of William Henry Willnas, Esq., of Kensington, and High Clyffe, Seaton, Devon.

Deaths.

BROWN.—Jan. 20, at his residence, 25 Dublin Street, Edinburgh, William Brown, F.R.C.S.Ed., aged 90.

CHESSALL.—Jan 19, at his residence, Horley, Surrey, William Chessall, M.D., aged 56.

FINLAY.—Jan. 27, Dr. Alexander Finlay, of Swanlinbar.

KENNEDY.—Jan. 24, at his residence, 8 Rutland Square, Henry Kennedy, M.B., F.K.Q.C.P., aged 75.

O'CONNELL.—Jan. 22, Dr. O'Connell, of Kilmallock.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

THE

Lettsomian Lectures

ON

SOME OF THE MENTAL AFFECTIONS OF CHILDHOOD AND YOUTH. (a)

By J. LANGDON DOWN, M.D. Lond., F.R.C.P.,
Senior Physician to the London Hospital.

ABSTRACT OF LECTURE III.

(Concluded from page 92.)

THE treatment of the various phases of feeble-mindedness resolves itself into medical and physical, and training, both moral and intellectual. The importance of commencing this betimes cannot be too much insisted on. Early training is of importance in preventing the growth of bad habits which become engrafted in the child. Constantly one meets with children who grow up a trouble to themselves and to those around them, from the injudicious treatment of some ignorant nurse who tyrannises over the family by her supposed essential relation to the child. Much time is often required to undo the evil—even if it be capable of being counteracted. There are two great hindrances to the early and successful training of feeble-minded children arising from misconceptions on the part of many members of the medical profession. It is constantly said to the anxious parents of these children, "Do not be troubled, the child will grow out of it; wait till he reaches seven years," or, if the child has reached that age, then wait till he has reached fourteen. I know nothing of cataclysmal improvements, such as are here indicated. The opinion and advice have no bases in experience. The septennial periods here referred to are periods of anxiety and peril; they are not periods of sudden leaps from mental feebleness to mental vigour; they are, on the contrary, developmental crises full of danger, periods when wreck of what mental power exists is liable to take place.

The other great mistake in the medical advice which is often given is the insistance to the mother that her child should not mix or be trained with children like himself, but with more intelligent children. Now, flattering as this may be to the parents, it is thoroughly baneful to the interest of the feeble-minded little one. The most successful training is effected with the child's equals; in this way a healthy emulation is established. Intelligent children will not take part in the amusements and games of feeble-minded ones. Moreover, there is no community of feeling or of interest. The outcome of an attempt to train the feeble-minded child with others more intelligent than himself is infallibly to make his life *solitary* and to accentuate the condition which it is of the greatest importance to correct. I have seen the relative of a nobleman, living in all the luxury of a well-appointed country house, so put aside by her sisters, junior as well as senior, that she never ventured on a remark, and at length lost speech. I have seen the same girl transferred to a class of children like herself, pass from monosyllables to thoroughly conversational language amid the sympathy and companionship of her compeers. Mothers of feeble-minded children invariably think their children more intelligent than any others of a like category, and they only need the bias of medical opinion to put off proper and effective aid until it is too late. Being afraid of their association with others of the same class, the parents either send them to schools where their life is made wretched by teasing, and where they fall hopelessly behind, without the benefit of individual skill, or the helpfulness of collective emulation; or the boy is relegated to a country vicarage or Welsh farm, without any of the appliances or agencies which can develope his best possibilities. The first thing to be done is to rescue the feeble one from this *solitary* life, to give him the companionship of his peers, to place him in a condition where all the machinery shall move for his benefit, and where he shall be surrounded by influences of art and nature calculated to make his life joyous, to arouse his observation, and quicken his power of thought. No one who can speak from experience in the matter would hesitate in saying that the companionship of their equals in intellectual power provides just the attrition which is desirable,—that the association with their superiors condemns them to a life of isolation which renders nugatory all efforts for their improvement. The fear that the association of a feeble-minded child with feeble-minded children will exercise an injurious effect upon the growth of intelligence is incorrect and not based upon experience.

Dr. Ireland has very well expressed that "imbecile children are no more injured by the presence of others of inferior intelligence than ordinary boys and girls are made childish by the appearance of a baby in the house,—that it is often, indeed, a great advantage for children to get rid of the uniform and hopeless inferiority in which they have hitherto lived, and to find that they have equals with whom they can interchange their simple ideas, and who give them a ready sympathy, and even to find that they have inferiors."

Those who have witnessed the transformation in children who have been removed from squalid cottages to a well-regulated institution, or have seen their joyous return from luxurious homes to their companions and their training, will be able to realise how truthful is a mother's account of her boy that, "When putting him to bed the last night he was smiles all over, saying, 'Going back to school to-morrow, mother,' and he packed his own bag before I could get to him in the morning, and could hardly finish breakfast, he was in such a hurry to be off, and went away all smiles and delight."

It must always be kept in mind that the basis of all treatment should be *medical*. Medical, I mean, in an enlarged sense. Success can only be secured by maintaining the patient in the highest possible health. This is very well indicated by the intellectual torpor which follows or accompanies declension of health, and the lessened intellectual vigour which is met with in cold weather. I have referred to the hibernation which occurs among many feeble-minded children, and which has led me to notice that their intellectual vigour is *directly* as their external temperature. The pallor of the cineritious portions of their brains, which is so frequently met with, is suggestive of the importance of vigorously maintaining their nutritive life. A very liberal dietary is of great importance. It should contain a fair quantity of nitrogenous elements, and be rich also in phosphatic and oleaginous constituents. Green vegetables are very essential, as in their absence there is a great tendency to become scorbutic. Care should be taken that farinaceous food, as represented by the so-called corn flours, should give way to the more plastic elements of nutrition found in semolina, entire wheat flour, or macaroni. Not only must the diet be sufficient in amount and good in quality, it should be exhibited in a form suited to their power of mastication. Their bedrooms and sitting-rooms should be spacious and well ventilated, and especially well warmed.

(a) Delivered before the Medical Society of London, Monday, Jan. 31st, 1887

The skin should be kept in healthy function by frequent sponge and other baths, not only for the sake of the individual health, but for the health and comfort of their associates. The exhalation from the skin of feeble-minded children is something *sui generis*. It is of great importance that their residence should be on gravel soil, and with well-made walks, that no opportunity may be lost for outdoor exercise. Warm clothing is essential, to prevent as much as possible the disastrous effects of climatic changes. I have before referred to the relative frequency of phthisis to the ordinary mortality.

Simple automatic movements, which I have referred to as being so common with the feeble-minded, should be replaced by others which are the product of will. We have to commence with very simple movements, gradually making them more complex. The want of co-ordination in the muscular system is very characteristic of the feeble-minded, and it is only by judicious physical training that the mutiny of the muscles can be overcome, and that purposeless acts can be converted into voluntary efforts suited for the wants of daily life. This training has to be carried out in great detail so that every voluntary muscle and every system of muscles may be called eventually into action. In this way the various acts of prehension, locomotion, and mastication are taught, the tongue becomes a willing agent, and the lips learn to retain the saliva which before gave our patient a repulsive look. I cannot enforce too strongly that little progress is made in speech until we first attain co-ordinated movements in their limbs. Finger lessons are to precede tongue lessons. I always remember the pinioned Frenchman who entreated that his arms might be freed because he wanted to speak. Unless we succeed in unpinioning the arms of our patients they do not speak. It is to be remembered too that we cannot bring into harmonious relation the muscles and the will without improving the physical quality of the brain and the other nervous centres. By these means, too, we shall have placed our patient into practical relation with the external world and initiated reasoning power.

The *moral* training is of great importance. He has to be taught, while his physical and mental powers are being developed by hygienic and physiological processes, to subordinate his will to that of another. He has to learn obedience; that right-doing brings pleasure, and that wrong-doing is followed by its deprivation. The affective faculties should be so cultivated that the deprivation of the love of the teacher should be the greatest punishment, and its manifestation the highest reward. In this way indications of untruthfulness, selfishness, obstinacy, sensuality, theft, and unkindness to companions are checked. Corporeal punishment should be strictly forbidden. The tact of the teacher will be called into exercise in devising the suitable reward or punishment. I have seen a girl exhibiting violent obstinacy melted into contrition and obedience by the threat of the teacher that she would wipe from her face the kisses she had given her the previous day. In no case should the punishment interfere with the hygienic treatment. Nothing is worse than the deprivation of food for an offence. I have seen a case of violent and uncontrollable temper reduced to calm obedience by the administration of a basin of bread and milk. The moral delinquency was the result of mental excitement, the outcome of defective nutrition.

The *intellectual* training must be based on a cultivation of the senses. They should be taught the qualities of form and relation of objects by their sense of touch; to appreciate colour, size, shape, and relation by sight; to understand the varieties of sound when addressed to the ear; the qualities of objects by their taste and smell.

It is desirable, however, to supplement the house and school by gardening and farming operations; by the lathe, the fretwork machine, the carpenter's bench, and, for the more advanced in education, the printer's shop. For girls, Kindergarten occupations and the various elegancies of needlework may be the outcome of persevering endeavours, while music and dancing may for all alternate with dramatic entertainments, which are most useful in appealing both to the eye and the ear. Care should be taken that the physical should interchange with the intellectual training. It is of the greatest importance that the teacher should keep clearly in view that his primary object is to make the pupil self-helpful, and, as far as possible, a useful member of the community; in this way more is done than by any other means. Mere *memoriter* knowledge is of little value; everything which makes him practically useful, makes him proportionately happy.

But I am warned that my allotted time has expired. Methinks medicine of these later days, which has signalised her march by numerous victories, has had no more beneficent result than has been achieved by the enthusiasm of such men as Howe, Seguin, Wilbur, Knight, and Conolly of the past, and by those still living who are followers, it may be at a reverential distance, in the work of rescuing from oblivion and neglect a class who appeal to our tenderest sympathies and our most affectionate regards.

NOTES FROM THE

HISTORY OF MEDICINE AND OF MEDICAL OPINION

FROM THE EARLIEST TIMES.

By Surgeon-General C. A. GORDON, M.D., C.B.,
Hon. Physician to H M. the Queen.

(*Conclusion.*)

The word science is used mainly in the sense of information as an equivalent to a body of ascertained truths, as having to do with doctrines. The word art is used in the sense of practical knowledge and applied power. The relation which they severally bear to practical medicine has been thus compared and contrasted by the late Dr. John Brown, namely:—

Art.	Science .
Looks to symptoms and occasions.	Looks to essence and cause.
Is therapeutic and prognostic.	Is diagnostic.
Has a method.	Has a system.
Is ante-mortem.	Is post-mortem.
Looks to function and structure.	Looks *vice-versa.*
Runs for the stomach pump.	Studies the phenomena of poisoning.
Submits to be ignorant of much.	Submits to be ignorant of nothing.
Acts.	Speaks.
Invents.	Discusses.
Is founded on experience.	Is antecedent to experience.
Has rules.	Has laws.
Is strong in organic life, and dwells in the *non-ego.*	Is strong in animal life, and dwells in the *ego.*
Apprehends.	Comprehends.
Makes knowledge a means.	Makes knowledge an end.
Is effect.	Is cause.
Is man *acting* on nature.	Is nature *speaking* to man.

Wisdom uses both, and is stereoscopic, discussing solidly as well as surface, and seeing both sides, its vision being the *unum quid* of two images (Lock and Sydenham, pp. 196-200).

A review of the history of medicine, as shown in the preceding summary, indicates that, among others, the following theories regarding disease have successively prevailed, and in turn been abandoned during the period of time over which the remarks extend, namely: —

1. In ancient Egypt diseases were ascribed to the moon and to the sun.
2. In ancient Greece to Divine wrath.
3. Subsequently, to atoms and elements.
4. To "Nature" and epidemic constitution of the season.
5. To coction of the humors (Fermentation ?)
6. That experience alone was necessary in medicine (Empirics).
7. That, in addition, reasoning and analogy were no less so (Dogmatists).

8. That drugs were inefficient.

9. That disease was due to obstructed pores and irregular distribution of atoms.

10. That as diseases differ, arising from the "constrictum" or the "laxum," so must their treatment (Methodists).

11. That health, and also disease depended upon the *pneuma* (nervous influences?)

12. That disease depended upon the state of the fluids and temperaments (Humoralists).

13. That treatment was to be conducted on the principle of "similia similibus" (Homœopathy).

14. That drugs were to be given in "geometrical proportions."

15. Clinical observation was trusted to rather than theory.

16. Medical theories were more attended to than experience.

17. Wounds were treated on the "moist" method.

18. Wounds were treated on the "dry" method.

19. Reasoning on abstract questions, in the absence of facts, prevailed.

20. A connection between the human body and the planets was held to exist.

21. Disease was assigned to the veins.

22. Noxious humors were believed to flow to diseased parts.

23. Disease was considered to be caused by the metastasis of noxious humors.

24. They were considered to depend upon a subtraction or minus.

25. Their causes were sought for in the planets.

26. Plague was attributed to the conjunction of Saturn, Jupiter, and Mars.

27. Plague was attributed to a putrid condition of the blood (blood-poisoning?).

28. Functions and disease were again assigned to the veins.

29. Treatment was conducted on the theory of "revulsion."

30. Treatment was conducted on the theory of "derivation."

31. A knowledge of disease was deemed unnecessary; "Natura medicatrix" cures.

32. The body was deemed to be affected by certain "entities," and dominated by an "archæus."

33. The laws of living body were explained by the laws of chemistry.

34. The pulse was looked upon as a preferable diagnostic to the urine.

35. The "superstition of numbers," otherwise critical days, according to Plato was reintroduced into medicine.

36. That an *archæus* produced fermentation in the blood, whence arose the "aura vitalis."

37. The self generation of poison in wounds was accepted as fact.

38. Plague was assigned to "some local corruption of the air."

39. One set of diseases were assigned to "acidity," another set to "alkalinity" of the humors.

40. The question of "inborn poisons" and of "specific diseases" therefrom, was discussed.

41. Disease was assigned to "an effort of nature to emove some noxious cause" (zymotic?).

42. Certain diseases were deemed to be "specific" in their nature.

43. A return to clinical observation instead of theory was welcomed.

44. Vital functions were explained by the laws of hydrostatics and hydraulics.

45. The "anima" of the Vitalists resembled the "archæus" mentioned above.

46. In man, animal life was assigned to the soul; in animals, to mechanical laws.

47. The theory "of nervous influence replaced that of the anima."

48. That of "fluids" and "solids," as seats of disease, replaced the theory of "strictum and laxum."

49. That of the "humors" was replaced by the theory of "solidism."

50. Out of the humoral and mechanical theories a third arose, combining both these.

51. The latter theory was succeeded by that of "irritability" and "sensibility."

52. It by the doctrine of the "semi-animists."

53. It by the theory of "vis medicatrix naturæ."

54. It by the "vital action of parts, more especially of the capillary arteries."

55. It by "a system of rational empiricism."

56. It by the theory of "excitability," "sthenic," and "asthenic diseases."

57. At the same time homœopathy with its potentiality or dynamitisation of drugs.

58. The doctrines of the Humoralists, Solidists, and Vitalists were combined to form a fourth.

59. The delusive doctrine of "irritability" was removed.

60. The value of drugs was recognised without seeking for occult causes.

61. The "nervous liquor" was deemed identical with the luminous ether.

62. Clinical teaching became a requisite of medical education.

63. Actual knowledge of medicine was acknowledged not to increase in proportion to experience, and accumulation of experience.

64. It was acknowledged that successive systems of treatment ran through their respective periods of "expectation, success, and disappointment."

65. Little value was placed upon theory as compared with observation.

66. The homœopathic doctrine for a time languished, to spring up again.

67. That of "animal magnetism" also spread.

68. "Profound investigation" was mixed up with "fanciful mysticism."

69. It was acknowledged that in medicine "the benefit was rather in anticipation than in existence."

70. Hypotheses were used as a means of research.

71. Physiology and anatomy supplied a basis in medicine.

72. Fevers were assigned to "irritation" of the intestinal canal. This theory was soon "exploded," to recur after a brief interval.

73. Certain diseases were assigned to a "zymotic" origin (the fermentation theory of previous periods).

74. The doctrine of "specific poisons" recurred.

75. As also that of special organisms, microbes, &c., causative of diseases.

76. Mesmerism was replaced by "hypnotism," &c.

77. Homœopathy "advanced as it had never done before."

78. Hydropathic establishments multiplied.

79. "A scientific method" was introduced into the investigation and treatment of disease.

The history of medicine, a brief summary of which has been given in the preceding paragraphs, presents to the thoughtful student much to contemplate. A few such points may be alluded to. In the most ancient times to which history extends, natural religion led the people to ascribe diseases to the emblems of Divinity, then to Divinity itself. So with the introduction of the doctrine of "atoms" in philosophy, that doctrine was applied to medicine. Then followed the theories of nature, the elements and seasons. At a very early period particular conditions of the fluids or "humors" was deemed to occasion disease; under the several theories of "coction," fermentation, and zymosis, the same idea has at intervals recurred, and at the present time prevails. The doctrine of atoms was replaced by that of "obstruction," it in turn by that of constriction and laxity, pneuma, humors, and temperaments. Out of these the doctrine of *similia similibus* arose. It was succeeded by the mathematical school, and by a recurrence to the influence of the planets. With the advance of anatomical knowledge disease was ascribed to the circulatory system, a doctrine which was in turn succeeded by various theories in regard to the humors; but the influence of the planets still dominated the medical profession, notwithstanding all such "advances." The theories of blood-poisoning, and the relation of disease to the state of the blood vessels again came into play. After them those of "entities" of disease and of a dominant archæus. Again the theory of fermentation arose; with it were associated those of "poisons" and of corrupted air. As chemistry became established, its doctrines were applied to medicine, diseases being assigned to acidity or alkalinity as the case might be. Then there was a reversion to the several theories of an archæus, and with it reference to mechanical laws, to "strictum and laxum," to irritability and sensibility, and after a time to the "vis medicatrix naturæ." With the advancing knowledge of the mechanism of the circulation, disease was assigned at one time to the veins, at another to the capillary arteries; after which all the above named theories were arranged and combined in various ways, other theories arising out of those combinations, profound investigation being mixed up with fanciful mysticism. Once again were the theories of "poisons," to some of which was assigned a zymotic origin, at the same time homœopathy, mesmerism, &c., &c., began to spread more than they had hitherto done. Fevers were attributed to intestinal irritation, a theory which was speedily superseded, but only to recur. With the advance of microscopic knowledge of organisms, the theory of microbes, bacteria, &c., as causative agents of disease arose, and with that theory, "a scientific method of investigation," &c., was introduced into medicine, and for the time being continues, its great practical utility, like that of a good many other methods alluded to in the above enumeration, being—in the future.

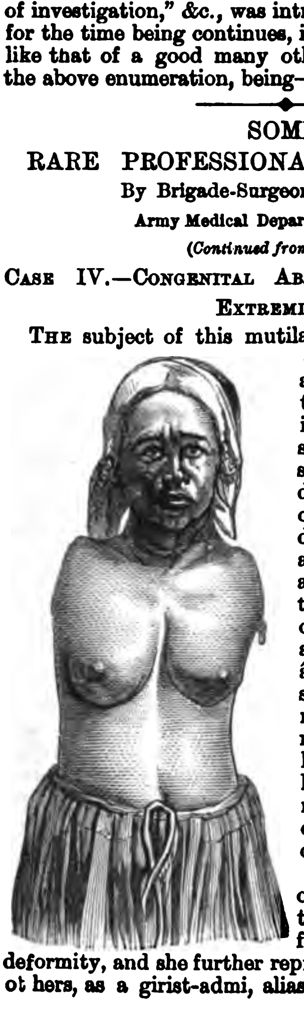
SOME
RARE PROFESSIONAL EXPERIENCES.

By Brigade-Surgeon W. CURRAN,

Army Medical Department (Retired.)

(Continued from page 47.)

CASE IV.—CONGENITAL ABSENCE OF BOTH UPPER EXTREMITIES.

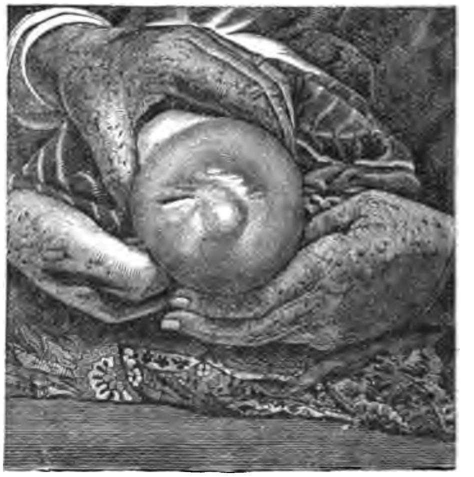


THE subject of this mutilation was a Hindu woman of 40, whom I met in 1861 at Shabjehanpore, and her then appearance is well illustrated in the figure subjoined herewith. A slight fleshy protuberance depends from the cicatrix of the humerus and shoulder-joint on the left side, and she informed me that a somewhat similar projection existed up to the age of ten on her right side also. It then dropped off âp-se, sahib (that is to say, spontaneously), she assured me, and this "survival" now measures one inch and a-half in length. It has a hardish, gristly feel, and may be regarded as the arm of a fœtus of three months of age.

She told me that she had one brother and three sisters, all of whom were free from this, or other forms of deformity, and she further represented herself, to me and others, as a girist-admi, alias, a villager or respectable married woman. I learnt subsequently, however that this statement did not accurately describe her condition, and that, like Edwin James's ballet-girl, she hopped on one leg and then on the other, and, that in short, she got her living, on occasion, between the two. (*a*) However that be, I was assured that when this saltatory device failed her, she picked up pice (small coins), in the bazaar and coram publico, with her toes. She either stuffed these, more simiorum, into her mouth, or shot them deftly over her left shoulder into a porringer that was held by a confederate behind her, and when this "business" slackened, she held—but in this instance only before a more select or aristocratic audience—a bottle at arm's length in front of her person, into which she ejected, for a consideration, the contents of her bladder. Whether a miss would be as bad as a mile in her case, or in this instance, I am now unable to say, but I know that considerable sums of money changed hands on these occasions, and the situation is otherwise and obviously one that admits of being more readily conceived than accurately described in these pages.

CASE V.—NATURE'S HANDYWORK.

A girl, age about six years, was seen by me in the Killarney Workhouse in 1872, whose leg had, I was assured on the spot, fallen off spontaneously, at the upper third or thereabouts, as a consequence of a localised mortification, the result of fever. She had, the good sister in charge of her informed me, suffered some three years previously or so, from an attack of fever—the form of which I could not ascertain—that greatly depressed her. While slowly recovering from this, she was suddenly seized with acute pain in the left leg, which swelled greatly, and soon assumed a purplish colour, as if, my informant added, she, the child, had drawn a red stocking over it. The part soon became gangrenous and offensive, and there can, I think, be no doubt about its embolic causation or origin. However that may be the surgeon of the house did not consider it safe to interfere—so I was told—and meanwhile, a line of demarcation having become established a little below the tuberosity of the tibia, the bones lost their vitality, and finally gave way one night. This process did not entail any conscious suffering or effort on the subject of it. The leg was, of course, found lying beside her in bed by the nurse of the day, and there was no bleeding at any time, either before this event or after it.



What remained of the skin and other structures was trimmed and brought into apposition by sutures and other suitable appliances, and the subjoined illustration —from a photograph that was taken under some difficulty by a local artist—fairly represents the present ('72) ap-

---

(*a*) Quomodo autem opus suum sexuale peregit, non audeo dicere, lector benevole, tantum incredibilitatis, forsan quoque et ludibrii, ei inest. Sed fortuito audivi eam, membrum virile, sinistri in digitibus pedis, amplexam, id,—heu! nefandum—in genitalia sua, ita inseruisse!

pearance and outline of this stump. When last seen by me she appeared to be in good health, and in a cheerful contented frame of mind. She flinched, however, when pressure was made on the part, and the projecting end of the tibia was, to my mind, insufficiently covered with skin.

It is not improbable that she may hereafter suffer from—if she has not done so already—a painful stump or a superficial neuralgia. Let us hope, however, that such has not been the case, and if you desire, gentle reader, to look up the literature of this kind of lesion, as well as to study the rude surgery of a bygone era, I would respectfully ask you to turn to my paper "On Natural Amputation and Spontaneous Fracture," that appeared in the *Lancet* of August 9th, 1873, pp. 189-222, &c., as well as to the following:—Article, "Amputation," in Lane's ed. of "Cooper's Dictionary," vol. i, p. 56, &c.; "Londiniana," by Edward Wedlake Brayley, vol. iii, pp. 68-72; "Letters on the Manners, &c., of the N. A. Indians," by Geo. Catlin, vol. i, p. 172; "The History of Friedrick II of Prussia," (a) by Thomas Carlyle; "A New Voyage round the World," by Capt. Wm. Dampier, vol. ii, pp. 77-8; "The Indian Annals of Medical Science" for July, 1873, p. 100; "Scott's Tales of a Grandfather," ch. xiv., p. 52; and Southey's "Doctor" (Longman's ed.), pp. 303 and 322.

Case VI.—"A Rude Awakening indeed, my Masters."

M. A., æt. 20, the subject of the curious recto-vaginal injury here contemplated, sustained this under the strange, if not unique, conditions set forth below. It appears that while she was carrying a bundle of clothes, which prevented her from seeing objects in front of her, she had occasion to pass over a style, at the opposite side of which a goat was lying. Irish girls of her class do not, I believe, usually wear drawers or other protection between the chemise and the trunk, and the great apertures of the body were in her case, or in this instance, fully exposed by the effort this ascent entailed. While in this enforced attitude, the goat, which was probably frightened by her approach, suddenly started up, and in doing so, thrust his horn forcibly through her anus, for about two or more inches up her rectum. Forcing it thence through the bowel and its coverings into the vagina, just above the hymen he withdrew it, as she flinched and fell back, by way of this passage, and in doing so produced a wound that included the lower part of the rectum and vagina, as well as the sphincter ani, the fourchette, and the perinæum. This wound bled freely, and caused excruciating pain. The subject of it fainted away from hæmorrhage and shock on the spot, and had to be carried in an unconscious state to bed.

Such is the modesty of my countrywomen, or so remote was the residence of this poor sufferer, that medical aid was not immediately sought for or procured in her case, and when seen three days afterwards by my informant, Dr. Hayes of Tralee, she was found to be in a highly feverish state. The pulse stood at 120, the skin was hot and burning, and the stomach was very irritable. The abdomen was tender and tympanitic, the intellect was slightly clouded, and needless to add, the tissues of the perinæum and vagina were greatly tumefied. Some antiphlogistic treatment, combined with local applications, having reduced the fever and relaxed the swelling, the edges of the wound were renovated and brought together with three deep and four superficial wire sutures. Rest in the recumbent position was enjoined, and opium was exhibited to control the bowels. She did well in due course, and after a small fistula that supervened had been closed by means of nitrate of silver, and with the exception that the perinæum was somewhat shorter than it ought to be, while there was some puckering between it and the anus, there was no other disfigurement or deformity. What her subsequent history is or was I am now unable to say, but let us hope it is or was a satisfactory one; and this, gentle reader, is about the rudest awakening of its kind I have ever read or heard of.

Foreign Department.

SALOL IN ARTICULAR RHEUMATISM.

By Professor HERRLICH, of Berlin.

An address on salol and its employment in articular rheumatism and other acute febrile diseases was delivered before the Berlin Medical Society on Jan. 10th by Dr. Herrlich. He first referred to the investigations made by Nencki and Sahli into its composition and therapeutical effects. According to these observers it is a salicylate of phenic ether, resembling fat in its behaviour in the system in being decomposed by the pancreatic ferments into free acid and alcohol—salicylic acid and phenol. Salol is a colourless crystalline body with a weak aromatic odour, is almost tasteless, and practically insoluble in water. It never produces nausea, like salicylate of soda, and is more readily taken. Sahli treated nearly all the cases of articular rheumatism in the poliklinik with it in daily doses of 6 to 8 grammes in individual doses of 2 grms. each. It was always well borne in these doses. A strong salicylic acid reaction was found in the urine two hours after the first dose. There was no fear of carbolic urine appearing after the doses given. The drug contained 40 per cent. of phenol and 60 per cent. of salicylic acid. There was no doubt that the antipyretic action was due mainly to the phenol. Singing in the ears was not always avoided, nor were endocarditic complications.

In addition to the good effects in acute and subacute articular rheumatism, a prompt action was observed in several cases of neuralgia in which salicin had proved inert, and also in *erythema nodosum* and *multiforme*, urticaria, and peliosis. In phthisis Sahli recommends it in doses of only 0·5 grm. It is useful in all cases of diabetes.

Further indication for its employment on account of the local antiseptic action of both its constituents as set free in the duodenum were noticed. It is highly probable that it acts antiseptically in the intestinal canal, and it will therefore probably prove useful in intestinal catarrh, typhoid, and cholera.

Syphilitic and other ulcers were rapidly healed by being painted several times a day with salol in powder. It was also found useful in ozæna and otorrhœa, and a 3 per cent. solution formed an agreeable antiseptic mouth wash.

Herrlich had used it in 25 cases of acute articular rheumatism, in a series of cases of chronic rheumatism, and in some cases of muscular rheumatism, lumbago, &c. It showed itself of decided benefit in the acute form. He could not say what part the carbolic acid played; in any case, the action was so rapid and striking that 6 grammes of salicylic acid did not correspond to it, so that it might be assumed that the carbolic acid played a part in the rapid improvement. Relapses and endocarditic complications were uninfluenced by it.

◆

PAROXYSMAL HÆMOGLOBINURIA.

By Dr. BAMBERGER, of Vienna.

Before the Royal Society of Physicians of Vienna, on 4th December, 1886, Herr Hofrat von Bamberger read a paper on Paroxysmal Hæmoglobinuria. After speaking of those cases of hæmoglobinuria that follow the introduction of mineral acids, glycerine, and other substances, and that accompanying the serious infective diseases, he went on to speak of it as occurring in healthy individuals who have been exposed to a severe chill, or who have made forced bodily exertions. The individuals become feverish, and are seized with a feeling of chilliness, or even a shake; finally, heat follows, and more rarely perspiration; often gastric symptoms and head-aches follow. The urine appears bloody, and shows, when tested by the spectroscope, the absorption stripes in yellow and green; nevertheless, it contains none, or only a few blood corpuscles; some hours after, a day at the latest, it has attained its normal qualities again. The whole complex of symptoms reappear on repetition of the cause. As an illustration Bamberger presented a coachman, æt. 45, who for two years got an attack; each time he had sat on the box in cold weather. During the interval between the attacks his urine contained no albumen; further chemical analysis was proceeded with in Professor Ludwig's laboratory. The patient showed a light jaundice colour. The appearance of jaundice in several cases proves, as the speaker claimed, that bilerubin can be formed either in the blood or in the tissues out of hæmoglobin.

Clinical Records.

LIVERPOOL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.

Case of Abscess of the Lung—Operation. (a)

By **Bernard Blower**, L.R.C.P. Lond., M.R.C.S.,
Stipendiary Assistant Physician to the Hospital.

The patient, J. L., æt. 36, a carter, was admitted into the Chest Hospital on Feb. 23, 1886. He had always, until the present illness, been a healthy man, but very intemperate. He complained of pain in the left side of the chest and shortness of breath, with slight cough. He stated that about two months previously he got a severe wetting, and was obliged to sit all day in his wet clothes, and on arriving home he was seized with severe pain in the left side of his chest, and had a shivering fit, and the following morning, although he had another shiver, went to his work and continued working for a fortnight, but at the end of this time was obliged to give up. I think he was able to continue working so long by keeping himself constantly under the influence of stimulants, in fact he was slightly drunk when he came into hospital. He was admitted under the care of Dr. Samuels. On examination scarcely any movement could be discovered in the left side of the chest, there was wooden dulness all over on percussion, anteriorly and posteriorly; the breath sounds were tubular throughout, and the vocal resonance and fremitus increased. The cardiac impulse was raised about an inch in position, but the heart sounds were normal. The right lung was healthy, except that the breath sounds were exaggerated. He had very little cough and hardly any expectoration. His temperature on the night of admission was 100°, the following morning 98·2°. Blisters were ordered to his chest together with other treatment. Four days after his admission his temperature rose to 103·8° at night, but fell to 99° in the morning. He had no rigor. Shortly after this he began to have night sweats, and his expectoration became more free and had a slightly fœtid odour, he was therefore ordered an antiseptic inhalation. These symptoms gradually increased, although no difference could be discovered in the physical signs of the lung, until about a month after admission into hospital, when there appeared to be a slight difference in the percussion note posteriorly, it being of a less wooden character, and the tubular breath sounds could not be heard over a limited area, and vocal resonance was also absent. At the wish of Dr. Samuels I introduced an aspirator needle between the sixth and seventh ribs, about the post axillary line, this being about the centre of the area before mentioned, and drew off about ʒij of fœtid pus, after which no more could be obtained, even though a return stream of carbolic solution, 1 in 40, was sent in to clear the needle. The following morning a considerable amount of swelling was found to have taken place around the site of the puncture, and distinct fluctuation could be felt. We, therefore, decided to make an incision between the ribs into the pleural cavity. This was accomplished with considerable difficulty, as the ribs were about three inches from the surface of the skin, the cellular tissue being swollen with exuded pus. I made an opening about 1¼ inches long between the sixth and seventh ribs, and about ʒiij of pus came out. The cavity was washed out, and a small drainage tube inserted. The temperature, which had been 104° the previous night, fell to 102·2° that evening, and the patient complained of very little pain. He went on well for nine or ten days, his temperature becoming almost normal, &c., but at the end of this time it was noticed that all the fluid injected in washing out the cavity could not be drawn off again, the temperature also rose higher at night, and although the patient could lie comfortably for some time upon his left side, yet when he turned over on to his right side, he was immediately attacked with violent dyspnœa and cough, and expectorated a quantity of fœtid phlegm. It was, therefore, decided to resect a portion of the rib, and open up the abscess cavity thoroughly. At this time it was thought to be a localised accumulation of pus in the pleural cavity communicating with a bronchial tube. The following day he was put under the A, C, E inhalation mixture, and Mr. Henry Samuels, Honorary Surgeon to the Hospital, made an incision a little below the original one, down the seventh rib, the periosteum of which was stripped off, and about two inches of the rib removed. The intercostal artery was divided, but was secured without any trouble. At the bottom of the wound was found a tough membrane, through which distinct fluctuation could be felt. The incision through this required to be made deeper than was anticipated, being through about ¾ of an inch of thickened pleura; the parietal and viseral layers of which were quite adherent. The incision opened up a large abscess cavity, about the size of an orange, from which a quantity of fœtid pus came out. Of course it was now very evident that this was an abscess in the substance of the lung, and not what it had been thought to be. The cavity was washed out with a solution of perchloride of mercury, 1 in 500, and two drainage tubes inserted, each about four inches in length reaching to the bottom of the cavity, and the wound dressed. The patient went on well for a fortnight; the abscess cavity contracted, although the discharge continued free, and the drainage tubes were kept well down to the bottom; the cough and expectoration became less; the night sweats decreased; and he gained a little flesh, in fact he appeared to be doing so well that he was very anxious to sit up. But on the evening of the fourteenth day he was suddenly seized with an epileptiform attack, which lasted about half an hour, and when he recovered consciousness he had complete paralysis of the right arm. The next morning he had quite recovered his senses and could speak distinctly, although he was much depressed. There was no rigor or high temperature previous to the attack. He remained in much the same condition for about six days, and then had another attack, after which he never became conscious, and was completely paralysed, and died five days afterwards. He never had any spasm or twitching of any muscles except in the epileptiform attacks. His temperature at the time of death was 105°.

Post-Mortem Appearances.—The left lung was collapsed and situated chiefly at the upper and posterior part of the thorax, and was there firmly adherent to the walls. The large abscess cavity showed fairly healthy granulations, and was reduced considerably in size from what it had been at the time of operation. In the upper part of the lung were a number of small secondary abscesses. The pleura was immensely thickened, and through its substance passed a sinus joining the original incision with the abscess cavity. The right lung was healthy. The cardiac valves normal. In the substance of the left hemisphere of the brain were found in all five abscesses, varying in size from a hazel nut to a walnut, and the left lateral ventricle was full of pus owing to the bursting into it of one of the abscesses. The cerebral membranes were normal. All the other organs in the body were healthy, with the exception of the liver, which showed signs of commencing cirrhotic change. There were no other secondary abscesses.

Remarks.—I have no doubt that the disease originated in pneumonia, and that this gave rise to the abscess which, from its close proximity to the pleuræ, caused inflammation of that membrane, and adhesions chiefly around the site of the abscess. That the abscess burst into the pleural cavity at this point, and that this was what was opened at the first operation. After a time the cavity began to granulate and contract, and the passage from the abscess to the external wound became almost closed, and thus allowed fluid to be forced in, but not withdrawn. There can be no doubt that the cerebral abscesses were of embolic origin, but what I consider to be the interesting point in the case is, why should they only occur in the brain. This, I believe, is usually the case with all abscesses in connection with the lungs and pleuræ. Of course the brain is more in the course of the direct blood-stream from the heart, but this is also the case with infective abscesses in other parts of the body, which give rise to secondary abscesses in other organs, such as the liver, &c., and in this case particularly, where eleven days elapsed from the first epileptiform attack to the time of death, there was plenty of time for abscesses to form in other organs if the necessary emboli had been carried to them.

ACADEMY OF MEDICINE IN IRELAND.

Pathological Section.

Meeting held Friday, Jan. 14, 1887.
The President, Dr. Walter G. Smith, in the Chair.

ASPERGILLUS NIGRICANS.

Mr. Story exhibited and described microscopic specimens of aspergillus nigricans, which he had removed from the meatus of three individuals suffering from deafness and inflammation of the external ears. Mr. Greenwood Pim had seen two of the specimens and corroborated the diagnosis. Mr. Story exhibited also a fourth fungus of an undetermined character, but most probably also one of the aspergillus tribe. He gave a brief *résumé* of the literature of the subject of otomycosis, and stated his conviction that the fungi were the cause and not the consequence of the ear disease—a view which had been advocated by some of the writers on the subject.

The President said he had seen a few cases of aural fungi. One of these was that of a gentleman who consulted him about a year ago for very intense pain in his left ear. He found the meatus partly blocked up with white cottony material. A brother of that gentleman was at the same time being attended by Mr. Swanzy for otomycosis, which was contracted by lying on hay or damp vegetable matter in the summer time, and he (the President) asked Mr. Swanzy to see his case. It was impossible to resist the evidence that the fungus was the direct cause of the disease. The invasion by it of the deeper tissues had been conclusively proved. He would ask Mr. Story whether, in any of his cases, he had noticed a special cause which led to the production of the fungus, such as dealing with yeast or any contact with vegetable decomposing matter. The aspergillus, he believed, was not confined to the ear, but also occasionally found in the bronchial membranes.

Dr. Mapother mentioned that in the year 1880 he himself had an acute attack of this otomycosis. He had never suffered, either before or since, from any aural disease. One night he went to bed in a house in the suburbs of Dublin with his hearing perfect; and the following morning he arose almost completely deaf. He bore the affection for one day, and on the next consulted Mr. Swanzy, who, partly by means of forceps and partly by syringing, removed a quantity of white cottony material from his ears. Besides the deafness, the only sensations he had were stuffing and a sort of ramming, as if something like cotton wool was being pushed into both ears. The material removed from his ears was examined by himself and his friend, the late Dr. Richardson, and they both came to the conclusion that it contained aspergillus. Which of the seven or eight different forms it was he could not say; but as well as he remembered, it was like the first form described by Mr. Story The growth was named from its resemblance to the aspergillus, or holy-water sprinkler used in the Roman Catholic Church. After the extraction of the fungi from his ears, a week's washing with sulphurous acid lotion, they disappeared and never grew again. He had observed that the wall paper of the room, next to which he slept, was extremely damp and almost competely separated from the wall by the dampness; and he believed that it was that which produced the fungi. Since the wall had become dry no similar attack of mycosis had occurred to any one else occupying the room.

Mr. Story, in reply, said he remembered having, as a patient suffering from this disease, a farmer who, after sitting up all night with a sick cow, had stuffing and pain in his ears next morning, which were found to be caused by aspergillus.

DERMOID TUMOUR GROWING FROM THE CORNEO-SCLERAL MARGIN OF THE LEFT EYE.

Mr. Story exhibited a dermoir tumour growing from the corneo-scleral margin of the left eye of a middle-aged man. The tumour was of a pinkish-yellow colour, and had one long hair growing out of its centre. No other hairs could be detected, even with a magnifying glass. The tumour had existed ever since the man's birth, and remained quiescent until two months ago, when it began to grow over the surface of the cornea. It was a flat sessile growth, of a circular shape, about 4min. in diameter, half corneal, half scleral. In his opinion, it was to be regarded as a dermoid growth.

ŒDEMA GLOTTIDIS.

Dr. Christopher Nixon exhibited the larynx and trachea of a patient who had died under his care of what it is the custom to call œdema glottidis, occurring in the course of Bright's disease.

Mr. Doyle, in commenting upon the communication, gave the clinical history of a case of Bright's disease which had been under his treatment.

The President observed that whether or not the disputed point was conceded that in Bright's disease the large smooth kidney might, in process of time, change to the small contracted kidney, there was no difficulty in assuming that other cases might occur in which that change did not happen. Whether it might happen or not, it need not happen. He would have no difficulty in accepting a history of any number of years' duration of Bright's disease, and yet in finding a large smooth kidney after death. He did not think any one maintained that the large smooth kidney necessarily turned into the small kidney. The point in dispute was whether the small kidney ever represented a large kidney which had undergone atrophic change. But that a large kidney might remain so far an indefinite time was no subject of wonder. Had there not been cases of a much longer duration of the disease than four years in which the post-mortem showed a kidney of a large type?

Dr. Nixon, in reply, said the point to which the President had referred was a very important one. He had adverted to the fact of the kidneys in this case remaining large and white for so long a time, notwithstanding that it was held by competent observers that the small red kidney was to be regarded as a stage or form of kidney in Bright's disease which all other forms of kidney in that disease had a tendency to assume. Starting with the idea that there was, first of all, a certain amount of inflammatory change which led to exudation, the next stage would be a proliferation of the connective tissue in the neighbourhood of that; and consequently the result should necessarily be the large white kidney passing into the atrophic form of the disease. There were two essentially distinct diseases—that is, if, as was the case in most instances, they had an atrophic change occurring in a large white kidney, it was quite a different process and different form of disease from primary atrophy of the kidney. For instance, if they examined a large white kidney which had undergone an atrophic stage they would find that it did not present the distinctly red glandular appearance of the primarily sclerotic kidney. The cortical substance was not atrophied to the same extent, and they had not the same amount of connective tissue developed in it as in the primarily sclerotic kidney. The forms of Bright's disease of the kidney which were usually met with were, first, the large white kidney; secondly, the atrophied condition of that large white kidney; thirdly, the primarily sclerotic, or red glandular kidney of Todd; and lastly, a fibroid condition of the kidney which occurred as consequential to certain diseases of the genito-urinary tract, such as old prostatic disease, accompanied with stricture. The evidence did not show that the different forms of kidney that they met with in the disease in question, especially the red glandular kidney, were stages of the one process. An important point alluded to by Wilkinson was that 40 per cent. of the cases of small red kidney had not been attended with dropsy; whereas it had been proved by statistics that in 92 per cent. of the cases of large white kidney dropsy had been a prominent symptom. If the small red kidney were an advanced stage of the large white kidney, it had never been explained why it had passed the primary stage without the occurrence of dropsy. He thought the arguments were strongly in favour of the view that there were three primary forms of Bright's disease—viz., first, the large white kidney which, no doubt, in a certain proportion of cases, underwent atrophy; secondly, the primary sclerotic kidney with a character of intestinal nephritis: and lastly, the form of nephritis that was consequential upon prostatic or urethral disease. As to Mr. Doyle's question, the specimen had been in spirit since the 6th of January, and now presented a much more shrivelled appearance than when it was originally examined.

The Section then adjourned.

◆

LIVERPOOL MEDICAL INSTITUTION.

The seventh ordinary meeting of the session was held on Jan. 20th,

The President, Dr. **Nevins**, in the chair.

Dr. **Barron** showed a case of fatty heart in which the coronary arteries were gravely implicated.

TWO CASES OF CEREBRO-SPINAL MENINGITIS.

Dr. **Davidson** showed the spinal cord and medulla from two cases of cerebro-spinal fever. In one the whole of the spinal cord was covered with semi-organised lymph. In the other the inflammatory exudation extended over the whole of the cerebellum and pons, and the upper part of the spinal cord. Under a microscope was shown a stained preparation of the exudation, which was seen to be crowded with a short thick bacillus, not hitherto described. The first case was a young man admitted into the Royal Infirmary in Nov. 1885, with headache, delirium, high temperature, and great pain and tenderness in the back of head and neck. The limbs were stiff, and movement brought on pains in the back. Paralysis of the legs and bladder and hyperæsthesia followed. He died about the 19th day of the disease with serious pulmonary complications. The second case was a young man (Oct. 1886) with very similar symptoms. He had an extensive herpetic eruption on the mouth and cheek. He died suddenly on the 31st of the disease from respiratory paralysis. Dr. Davidson stated that he had treated about half a dozen cases of this disease during the last two years in the Royal Infirmary. The other cases recovered. In none of them was an eruption noted.

Dr. **Robertson** stated that he had treated eight or nine cases of cerebro-spinal fever in the workhouse infirmary during the last few years.

CASE OF ATAXIC PARAPLEGIA.

Dr. **Davidson** showed a man suffering from ataxic paraplegia. He was a bricklayer, æt. 33, who had syphilis twelve years ago, and was much given to sexual excesses. His illness began eight months ago with seminal emissions, occurring in the daytime, after exertion. Then numbness and loss of power in the feet came on. When first admitted into the Royal Infirmary last summer, his symptoms were partial loss of power in the legs, without loss of sensibility, slight weakness of bladder, speech slightly affected. The knee reflex and other reflexes of the lower limbs were decidedly exaggerated. There was increased sensibility to the hot sponge at the lower part of the spinal column. Since then the ataxic symptoms, which were slight at the time of his admission, had become much more evident, and rigidity of the muscles of the leg had become well marked. Also he had paralysis of the diaphragm. The patient, who was a strong-looking man, walked with some difficulty, the muscles of the legs being stiffly contracted and the heels drawn up from the ground. With his eyes closed he staggered and swayed about. Dr. Davidson pointed out that in this disease the symptoms of locomotor ataxy and spastic paralysis were combined; but that "ataxic paraplegia" was easily distinguishable from locomotor ataxia by the slighter amount of inco-ordination, the absence of the lightning pains, and the exaggerated knee reflex.

Dr. **Blower** brought under the notice of the Society a

CASE OF ABSCESS OF LUNG WITH OPERATION,

which will be found at page 118, under "Clinical Records."

Dr. **Rawdon** related a case of unusual congenital deformity of the nose.

Dr. **Alexander** read a paper on some points in the

PATHOLOGY AND TREATMENT OF CARIES OF THE VERTEBRÆ.

He had made post-mortem examinations in 53 cases, and the paper was founded upon the lessons to be learned from the specimens of spines thus obtained, many of which were exhibited. Of these cases 5 were affected by cervical caries, 21 by dorsal caries, 20 by lumbar caries, and 8 by caries at the dorso-lumbar junction. The causes of the disease were the writer believed, either traumatic or pyæmic, and several cases were cited to illustrate these two modes of origin. He did not believe much in hereditary predisposition, and pointed out by examples how dental caries, scalp eruptions, ear disease, and eruptive fevers constituted efficient causes in apparently spontaneous cases. The different pathological processes by which a cure of caries of the vertebræ occurred were next discussed. He believed that a sound cure by complete bony anchylosis of the bodies of the vertebræ was a comparatively rare event, much rarer than surgeons and pathologists now believed. The spines in several cases believed to be cured for half a lifetime, were shown, where large cheesy abscesses were found at the post-mortem. Anchylosis with acute angular curvature was almost as bad as no union, most of these cases dying at or before puberty from interference with the functions of the internal viscera. In all cases anchylosis began between the pedicles and between the articular processes as a result of increased pressure and of inflammatory action at these points. Thence anchylosis spreads backwards to the laminæ and forwards between the bodies after the diseased parts had been removed. Numerous specimens were exhibited to illustrate the parts that became anchylosed. A paper was promised to describe the mode of treatment most likely to be successful as indicated by a study of the pathology of the disease.

Mr. R. N. **Pughe** was glad to hear Dr. Alexander attach so much more importance to direct or immediate causes, *i.e.*, traumatic or pyæmic, of spinal caries and similar diseases of bone than to remote or ancestral causes. He held that the latter had little if any effect as a cause of these diseases, but more on their course. The initial lesion in most cases is distinctly traumatic in its origin. Subsequently in so-called strumous cases other bones become similarly affected or other tissues attacked. But he considered these secondary lesions to be evidences of chronic pyæmia, and not of any special tubercular disease. In fact, every variety may be seen, from rapidly fatal pyæmia following acute periostitis in a child (with or without septic pneumonia, meningitis, or other complications) to the most chronic form of scrofula. In some acute cases we find the symptoms subside and the disease taking upon itself a chronic course in the form of lesions exactly resembling those found in an ordinary case of scrofula; the difference being that in the latter the course of the disease has been chronic from the first. He saw no reason whatever for calling rarefying osteitis tubercular, its characteristics, tendency to caseation, &c., being due to the conditions under which the inflammatory action takes place, and the tissue-bone, which is attacked. This greater frequency of these bone diseases in children may be accounted for by the fact that in the growing part of the bones (subperiosteal tissues, along the epiphyseal lines, and under the joint cartilages), what may be called a natural hyperæmia exists. Here traumatic causes easily upset the balance of circulation, and bring on inflammatory action. Anyhow, it is on these, the growing parts of the bone, that bone and joint diseases in children almost invariably commence.

Mr. **Paul** also spoke, after which Dr. Alexander replied.

◆

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Meeting held Wednesday, February 2nd.

The President, Prof. **Grainger Stewart**, in the chair.

A large number of patients and specimens illustrative of

THE TREATMENT OF EMPYEMA

were exhibited, in anticipation of a paper on that subject by Dr. William Russell. Ultimately the paper was deferred to a special meeting, to be afterwards announced, as the hour was too far advanced when Dr. Russell was called.

Dr. Affleck, in conjunction with Mr. Cotterill, showed a case of empyema, cured by resection of five ribs. In September, 1885, the patient, a woman in middle life, had suffered from pleurisy with effusion, for which she was tapped. In June, 1886, she was admitted to Dr. Affleck's ward in a very low state of health, with more than one sinus, discharging pus, in connection with the left pleural cavity. She also expectorated large quantities of pus. There was an additional history of recent scarlatina, erysipelas, and pneumonia. After having her general tone raised, she was transferred to Mr. Annandale's wards, where Mr. Cotterill operated, in August, 1886, with the most perfect success. Dr. Affleck thought the operation specially indicated, on account of the absence of phthisical history, and because of the evident bad effects of the continual drain on the patient's system.

Dr. William Russell showed a case of cured empyema in a very young child, obtained by simple drainage and irrigation without resection.

Mr. John Duncan exhibited two similar cases. In the first he had resected eight ribs, from the third downwards. The operation was successful, though the result was delayed somewhat by the formation of an abscess in connection with the disturbed bones. A fresh portion of bone was removed, and the patient made a good recovery. In the second case, he merely resected one rib and inserted two drainage tubes. If the drainage tube were inserted into an opening made by simple incision without resection, he had found that considerable pain was apt to occur, owing to pressure. This pressure was sometimes so marked as to lead to grooving on the opposing borders of the two ribs. This difficulty was overcome by the resection of a small portion from one rib.

Mr. Francis Caird showed a child on whom the drainage system had first been tried, with the result that a troublesome sinus was left. Resection of a rib was then instituted, and the patient did well. Mr. Duncan's difficulty could be largely overcome by the use of a metal instead of an india-rubber tube.

Dr. Sims Woodhead exhibited part of the chest wall, pleural sac, and lung of a patient who had died of empyema. The abscess cavity reached upwards right behind the clavicle. Between the two adherent layers of pleura there was a septum of tubercular new formation, bounded on each side by a layer of fatty tissue.

DEATH THROUGH SWALLOWING AMMONIA.

Dr. Littlejohn exhibited the larynx, œsophagus, stomach, and intestine of a man who had died from the effects of swallowing, in mistake, 2¼ oz. of Bowes' liniment. The signs were those characteristic of irritant poisoning. It was doubtless known that the irritant property of that popular liniment was due to ammonia.

CASES OF SUDDEN DEATH.

Dr. Littlejohn drew attention to the comparative frequency of sudden death from cardiac disease, in which no distinct explanation could be obtained, apart from incompetence of the aortic valves. He showed three preparations obtained from cases which had occurred lately in his practice, where evident signs of atheroma existed, though in two of the instances the aortic valves did not appear egregiously incompetent.

AFFECTIONS OF STUMPS.

Mr. H. A. Thomson showed two stumps, where peculiar changes had occurred. In the first, there were evident signs of regeneration of the nerves below the point of section. The second, of which he had made frozen sections, showed the effect of growth of bone in the stump of a child. The stump had become typical conical.

MULTIPLE SEBACEOUS TUMOURS.

Dr. P. Maclaren showed a lad over whose head and body were almost universally scattered multiple tumours, varying in size and consistence. At first, he fancied it a case of *molluscum fibrosum*, but on section of the masses found they contained sebaceous material. Cases of so widely spread affection were extremely rare.

COMPOUND COMMINUTED FRACTURE OF UPPER AND LOWER JAWS.

Dr. Cotterill showed a patient who had made a marvellous recovery from a compound comminuted fracture of the upper and lower jaws. The angular process of the superior maxillary was splintered, the malar bone was shattered, the superior maxillary was broken transversely across, the hard palate was divided from front to back, the inferior maxillary bone was broken close to the junction of the ascending and the horizontal ramus, while several minor disturbances were present. Whatever bone appeared to have any connections was left, while the completely separated splinters were removed, and the parts brought into suitable apposition. The patient made a good recovery.

Professor Annandale then read a paper on

INTERNAL DERANGEMENTS OF THE KNEE-JOINT.

He detailed the result of eight operations. In the first four he had operated with perfectly successful results for detachment of one or other semi-lunar cartilage. He made an incision parallel to the head of the tibia, from the ligamentum patellæ, outwards or inwards according to the side, tied all bleeding vessels, and then cut into the joint in the same direction. He caught hold of the loose cartilage, drew it forward and stitched it to the periosteum. He believes that the internal cartilage was most frequently affected, and this often as the result of sudden strain or similar accident. He strongly advocated operation. The next three operations were for tumours, two fatty and one myelo-sarcomatous. In these the operation was similarly conducted, the tumour caught hold of and its pedicle stitched to the periosteum and either left, if small, or removed, if too large. In the last case he found a small outgrowth of bone from the end of the femur, such as occurs in chronic rheumatic arthritis. It measured a half-inch by a quarter-inch. This he removed successfully also. Mr. Annandale, further, gave details of similar results obtained in operation for dislocation of the fibro-cartilage of the sub-maxillary articulation.

Professor Grainger Stewart thought the paper most suggestive, and displayed much of that felicitous precision which characterised Mr. Annandale's operative undertakings.

Dr. Hadden thought more attention should be bestowed on manipulative interference in such cases. He referred to the triumphs obtained by bone-setters. There was reason in the method, and it should be thoroughly understood by authorised surgeons.

Mr. John Duncan feared that, in not a few instances considerable harm had followed the indiscriminate use of manipulative interference. He thought Mr, Annandale's paper one of much value. In a number of cases mechanical supports were often sufficient to correct the tendency to locking of the joint, and some patients naturally preferred this to operation. In cases which were really serious he had noticed a distinctly "tender spot" midway between the ligamentum patellæ and the internal lateral ligament.

Mr. Cotterill thought the characteristic symptom of locking of the joint was probably explicable by the fact that, in such cases, the semilunar cartilage, which normally had some movement, was too free, and when the knee was bent, slipped too far, and so was caught as the leg returned to extension.

Dr. Scott Lang referred to a paper published by himself in the *Edinburgh Medical Journal*, in which he had endeavoured to explain the mechanism by which locking was caused, and the *rationale* of its reduction.

Dr. Caverhill approved of an attempt at manipulative cure.

Mr. Annandale spoke highly of the work of Dr. Scott Lang. He did not approve of mechanical supports. Too much use was made of these in the South.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 9, 1887.

TYPES OF PURPURA.

In the current number of Dr. Richardson's *Asclepiad* the place of honour is held by an article which is likely to call forth a considerable amount of discussion concerning the views therein enunciated on the subject of scorbutic disease. Under this common heading there are included, Dr. Richardson contends, three distinct and separate diseases, which he denominates "types of purpura," "each having a distinct pathology, etiology, diagnosis, and prognosis, and each requiring a distinct treatment." These three affections are classified as—(1) the aqueous; (2) the saline; and (3) the vascular. In patients suffering from the aqueous type the characteristic feature is extreme fluidity of the blood, due to excess of water; they are often of good muscular physique, and an eruption is usually though not always developed, the exciting causes being numerous and varied. Such persons often go through life with comfort and apparent health; bleeding when it occurs is easily arrested, and recovery from loss of blood rapidly ensues, though Dr. Richardson doubts if ever the quality of the circulating fluid is ever quite natural. The disease is eminently hereditary, and its remote origin is associated by the author with the central nervous system.

In the second group of cases, "saline purpura," the salts of the blood are largely in excess, and hold the fibrine in undue solution, a condition variously induced, and markedly so as a consequence of long subsistence in cold regions on salted provisions, as was experienced by sufferers during the earlier Arctic explorations. Alcoholic indulgence is also a cause of the disease, and prolonged use of chloral, the decomposition of this drug leading to accumulation of formate of sodium in the blood. Dr. Richardson says he has met with four cases of saline purpura induced in this manner. The old-school "scorbutics" he considers to have been all examples of this type of purpura, which he regards as non-hereditary, and as being the consequence of improper diet or of a toxic habit. The eruption is a sharply-marked *macula*, more distinct than is that of the aqueous type, and occurring spontaneously, *i.e.*, without injury. The eruption here, too, may, however, be absent, but there is always a tendency to exudation of blood.

"Vascular purpura," the third type of the affection, is attended with a marked disposition to eruption, which is easily excited by the smallest physical injury, and which assumes the form of a large amount of discoloration, and some degree of swelling. Its subjects are very frequently young children, and it is not strongly hereditary. Those who suffer from it are often fat and well nourished, but as a rule present some deformity of body, such as spinal curvature, distorted limbs, or ill-developed chest. The blood is normal in its characters, but the vessels of the minute circulation undergo changes in which lie the causes of the affection, and which are in some way related to the innervation of the parts. In this connection Dr. Richardson offers a very lucid explanation, illustrated by very interesting cases in his own practice of the occurrence of so-called "stigmata," and next discusses the diagnosis of the types of purpura previously described by him.

Special interest will naturally attach to the author's recommendations as to treatment, and the essay in this respect is enriched with full and valuable details. The principle to be followed in the attempt to cure the aqueous form of the disease is clearly indicated in the directions to supply the patient with fresh animal food in fair amount, and to promote active excretion of fluids, free purgation being combined with administration of ferruginous tonics. The prescription Dr. Richardson here recommends contains syrup of superphosphate of iron and peroxide of hydrogen in glycerine and water. Moderate, but not severe, outdoor exercise is also advised. For immediate arrest of bleeding in these cases dilute sulphuric acid, with administration of good nutritious food is the plan always successfully followed during twenty years by the author, while he disapproves of caustic styptics, the colloid being in his opinion the most suitable application. For saline purpura, pure water in considerable quantity, moderate feeding, and complete abstinence from salted foods, is the treatment to be pursued, while medicinally dilute hydrochloric acid and peroxide of hydrogen are to be given. Styptics are forbidden, but for bleeding gums a wash of tannin, iodine, and myrrh is offered. The administration of turpentine is highly extolled in cases of the third type, or vascular purpura, together with good food, fresh air, and deprivation of alcoholic stimulants. The turpentine may be given in combination with iron in glycerine, or in capsules.

How far Dr. Richardson's conclusions and nomenclature will find adoption by the profession remains to be seen; but whatever the result in this direction may be, his essay is a very valuable and important contribution on a class of diseases not infrequent in general practice, and concerning the treatment of which especially his clearly expressed directions will be at once useful and acceptable.

THE ELECTION AT THE LIVERPOOL HOSPITAL FOR WOMEN.

The final stage in the proceedings at Liverpool in reference to the operative procedure at the Hospital for Women has now been reached. On Thursday last, the annual meeting of the Governors, &c., of that Institution took place, and after a very animated discussion Dr. Burton was re-elected by 13 votes to 9, while Dr. Imlach's re-election was negatived by 17 to 16. A poll was demanded on behalf of the latter, which confirmed the above result by 272 to 137. This result, which is an emphatic approval of the principles which we have laboured long and hard to bring to the front, is eminently satisfactory. Some months since, we, alone among the medical press, took up the cause and insisted on the necessity of an inquiry into the manner in which operations involving removal of the uterine appendages were decided upon and carried out at the Hospital for Women. Our perseverance was at length rewarded by attention being directed to the evils of which we complained, and after an exhaustive and impartial inquiry, the conclusion was officially arrived at that "sufficient care and discrimination had not been exercised over these operations." It is scarcely necessary for us to say that no personal feeling on our part *vis-à-vis* Dr. Imlach has prompted or stimulated our action. The question was simply and purely one of principle. Dr. Imlach's retirement had become necessary for the reason that his presence was incompatible with the harmony and proper working of the medical staff. Notwithstanding the resolution as to the advisability of making use of consultations before deciding on operations of this description, Dr. Imlach declined to seek the advice of his colleagues, and his attitude generally was such that, with every admiration for his skill as an operator, the Committee could scarcely venture to retain him in his position on the medical staff. Personal feeling, as evidenced by the proceedings at the meeting, ran high, but with this regrettable circumstance, we have nothing to do. We must congratulate Dr. Burton on having retained the confidence and esteem of the authorities of the hospital. At one time it seemed by no means improbable that he might be sacrificed to the resentment to which his own action in the matter necessarily gave rise. We are glad, however, to find that his *bona fides* and straightforwardness have not failed to produce the effect which they merited, and we hope now that the affairs and management of the institution have been placed on a new footing, a new career of usefulness will be opened to it and to its officers. It is always a disagreeable and rather ungrateful task to undertake and initiate a campaign like that which has now come to a conclusion. Many private interests are unavoidably attacked and feelings wounded, but the interests of the public, as represented by the patients who seek relief from suffering at these institutions, pass before and dominate any such considerations. Nothing short of a general and categoric expression of opinion on the part of the authorities of such institutions is sufficient to ensure the necessary inquiry and alteration, and this cannot be elicited without calling forth angry feelings on the part of the persons involved and their friends and supporters. We cannot forbear expressing our appreciation of Dr. Grimsdale's disinterested conduct in this affair. Guided only by the *mens conscia recti*, he discharged a very painful and thankless task in spite of obloquy and contumely. An attempt was made on Thursday to interpret unfavourably his line of action, but with commendable promptitude he nipped it in the bud. The history of this "epidemic" in Liverpool may serve to point a moral elsewhere. Without expressing any opinion on the merits of the operation, useful, no doubt, and even indispensable in a certain class of cases, the sense both of the profession and the public will always be adverse to its too indiscriminate performance. The sexual consequences as well as the mortality which attend it are sufficiently serious to warrant every precaution being taken against its abuse. Its bearings have been amply discussed, and the operation is now placed on a sound basis. The atmosphere has been cleared, and we trust that the antagonism which has rendered the Liverpool Hospital for Women a "bear garden," to quote one of the speakers, is now a thing of the past.

Notes on Current Topics.

The London Doctorate.

We hear that it is proposed to insert a clause in the scheme which is shortly to be submitted to the Queen in Council by the Royal Colleges of Physicians and Surgeons, to the effect that students desiring to take advantage of the new order of things will be required to afford evidence of residence in London.

We cannot too emphatically express our disapprobation of this illiberal idea. If there be one proviso more than another belonging to the old University system which might well be discarded, it is that which bears on residence. In the University system, it is true, residence has its *raison d'etre*, more or less, but it would be difficult to justify such a provision as applied to the College scheme. It is an undisguised attempt to coerce men into attendance at London Hospitals, and this at the expense of Bristol, Birmingham, Sheffield, &c., which ought to take immediate measures for their own protection.

We trust this clause will be repudiated immediately; failing this it will be our duty to see that it does not become law by intervening at the proper moment and pointing out the unjust restriction that would thus come into force. The examining board of the Colleges is the "examining board for England," and it would be unworthy of them to do anything which should make them merely a metropolitan concern.

There are several points on which the scheme may be wrecked of which the above is one. Another is the non-representation on the Councils of the Colleges, of the Professors at the London schools, and the government. It is possible that the anxiety of London men to obtain a degree of some kind may blind them to the injustice of their exclusion. Again, it seems tolerably certain that no future scheme for conferring degrees will be sanctioned by the Privy Council which does not provide for the admission of women. Last, but not least the exclusion of the Apothecaries' Society from the scheme must seriously imperil its chances of success as has been forcibly and even eloquently pointed out on various occasions. It is quite possible that questions may be asked in the House concerning these points, and that the matter may be taken out of the hands of the Privy Council.

The Erasmus Wilson Bequest.

The proposed appropriation of the Wilson bequest to the foundation and maintenance of a physiological and biological laboratory in connection with the Royal College of Surgeons has, not unnaturally, caused a great excitement in the anti-vivisection camp. In their organs and meetings no terms are too strong, no language too vehement, to qualify the proposed scheme, and it is evident that so far as lies in their power, no stone will be left unturned to prevent its being carried out. What effectual opposition it may be in their power to offer remains to be seen, but it would be a *reductio ad absurdam* if this irresponsible body of crotchet-mongers should be allowed to impose their veto upon a project which will do something to remedy the actual shortcomings of physiological research in England.

It is a rank absurdity to talk about or affect to anticipate a "signal deterioration of the moral tone of one of our greatest professions." Has the tone of the profession fallen since physiological research became a fundamental part of its work? He would be a bold man who would venture on any such assertion, seeing what the tone of the profession was when such researches were neither liked nor prosecuted. Fortunately knowledge acquired is permanent, and even if further progress be hindered or prevented, we are not likely to revert to pre-physiological days.

In spite of the foolish sneer with which they greet the alleged patriotism of the scheme, we still maintain that a flourishing and successful physiological and pathological laboratory will constitute a much better title to honour and merit in the eyes of posterity, than that of having possessed the largest, most influential, and most unscrupulous body of anti-vivisectionists in the world.

It is not our immediate concern to criticise the details of the scheme itself. This mode of utilising the munificent bequest of Sir Erasmus Wilson is not one which is sure to meet with approval even at the hands of those who see no crime in the prosecution of researches for the advancement of knowledge and the alleviation of suffering. Our object has been rather to resent the unwarrantable interference of people whose competence in matters scientific is proved neither by their acts nor their words. Whether the scheme be or be not ultimately carried into effect, the decision, it is to be hoped, will be based on considerations quite alien to the contentions of this or that "fad" society.

The Royal College of Surgeons has many advantages over the Universities for such a purpose. It is exempt from the clerical element which, in company with the old maids, has periodical hysterical attacks anent vivisection, vaccination, and the Contagious Diseases Acts. In every instance their associated influence has been used to stultify the benefits which medical science, in the persons of its adepts, seeks to confer on the public. Their want of logic and consistency only accentuates the feeling of resentment which one feels towards their machinations so often conducted without regard either to the accuracy of their facts or the legitimacy of their deductions.

Milk Diet.

The therapeutical advantages attending an exclusively milk diet in the treatment of certain diseases have received general confirmation, but like most other remedies, its employment requires certain precautions to be adopted if the good results are not to be obtained at the expense of some other ailment. It has been recently pointed out that the ingestion of more than two quarts of milk daily for, more than a short period of time, is likely to cause dilatation of the stomach with the whole train of distressing symptoms to which this gives rise. It is advised that where larger quantities than this are required to be taken, in order to keep up the nutrition, it is preferable to administer small quantities of meat together with small doses of an alkaline base after each ingurgitation. If the contents of the stomach be kept neutral, digestion takes place only in the intestines. If it be desired to avoid giving meat, the milk should be strengthened to the required degree by the addition of concentrated milk or evaporation. Not unfrequently means have to be adopted to aid the digestion of the lumps of agglomerated curd which form when the milk enters the stomach, and the size and consistency of which delay and interfere with the action of the gastric juice. The only remedy for this is pre-digestion by means of the pancreatic ferments, many good preparations of which are now in the market.

Representation of Dublin University.

It is almost certain that Mr. Attorney-General Holmes will shortly vacate his seat as Representative of the University on promotion to the Bench, and already several candidates, mostly lawyers, are preparing themselves for the contest and canvassing for support. We trust that the medical graduates will not give promises or in any way identify themselves with the contest between such candidates, until they have considered and ascertained whether an eligible candidate of their own cloth cannot be found. It has long been an opprobrium of Trinity College that it has been for many years the traditional warming pan for aspiring lawyers, who are ambitious to serve as its representative inasmuch as it is a highly respectable seat, a gentlemanlike constituency, very economical to contest, and an excellent spring-board for a jump to the Bench. Is it not time that a medical graduate should have a turn? He would be more recognisable as a scientist and an academician than most of the legal gentlemen who are bidding for the seat, and, therefore, more appropriate as the spokesman of a university in which science has always held first place. Moreover, it may be said that medicine is now the vertebral column of the University, inasmuch as the medical faculty has, in great measure, superseded the divinity school since the Irish church was disestablished, and neither the Engineering or Law Schools can at all compete with it in numerical importance. The Medical graduates, who a few years ago, were insignificant in number as compared with the Divinity graduates, are now a strong and influential body, and we know that there is a very strong feeling amongst the non-legal constituents of the University which would lead many of them to vote for any reasonably eligible scientist in preference to a lawyer. We should think that the medical voters can have very little interest in selecting one lawyer in preference to another, and that many of them, therefore, will decide to remain silent if they can find nothing better to do with their suffrage than to give one more plausible gentleman a lift to a government appointment.

The Jacob Testimonial.

We are requested by the Honorary Secretaries of this fund to acknowledge with their best thanks the receipt of several additional subscriptions, which will be found detailed in our advertising columns. They desire specially to draw attention to the widespread interest which the object has evoked, and to the representative character of the subscribers; upwards of a hundred of the less opulent having contributed side by side with the distinguished heads and titled members of the profession.

Naphthalin in Diarrhœa.

The treatment of intractable diarrhœa, if the association of terms may be permitted, is one of the puzzles which are probably more frequently met with by general practitioners than by any other class of the medical profession; and how to arrest the weakening outflow is oftentimes a question of the most anxious kind, all the reputed remedies being occasionally found powerless to aid. In recent years, however, a large advance has been made in the direction of an accurate appreciation of the conditions which bring about the occurrence of obstinate intestinal evacuations, and the recognition of the fact that they may be, and often are, due to the presence of minute organisms, is one of the most useful contributions made to our knowledge of disease. The logical consequence following appreciation of this truth is naturally an adaptation of remedial means appropriate to counteracting the evils produced, in which connection the use of antiseptic drugs is clearly indicated. In America, the profession has been taught to adopt such a view, and a number of physicians have recently recorded their experience of treating summer diarrhœa by antiseptics, and of all the substances so employed the most conclusive and satisfactory evidence was adduced in favour of naphthalin. An essential part of the treatment is the evacuation of the canal, with the object of discharging the material which the antiseptic medicine renders impotent, and the amount of naphthalin administered should, it is urged, not be too small. Less than sixty grains *per diem* for adults, is said to be of not much use, and one observer has given frequently as much as one hundred and twenty grains in divided doses, usually in starch capsules. In chronic diarrhœa its success is very marked; and the suggestion of course arises that it may prove equally beneficial in the diarrhœa of phthisis, intestinal catarrh of children, and in such diseases as typhoid fever, &c., in which disinfection of the alimentary canal becomes an object of the first importance. During a discussion on the use of naphthalin at a meeting of the New York Academy of Medicine, instances of its employment in cases of typhoid were reported, and the highest opinion was expressed of its utility under such circumstances, while a general agreement was evinced amongst the speakers taking part in the debate to the effect that the addition of the drug to the *amwamentarium* as a remedy in persisting diarrhœa was matter for congratulation. As compared with salicin and salicylic acid it possesses a decided superiority, and further experience with it seems not unlikely to lead to its more general employment. In this country it has not yet had any very extensive trial; but as the occasion arises practitioners may feel disposed to ascertain for themselves how far it is deserving of the praise it has received at the hands of their Transatlantic brethren.

The Assistant-Physicianship at St. Bartholomew's.

The vacancy in the staff at St. Bartholomew's Hospital caused by the resignation of Dr. Wickham Legg will probably be sharply competed for. Many candidates are in the field, and several of them are well known for their scientific and professional attainments. The Medical Registrar, Dr. Samuel West, is a candidate, and probably has a good chance of success.

It is to be remarked that the old custom prevails at this hospital of election by the whole body of governors. This system has many disadvantages, and a proper selection would be easier to make by a more purely medical committee, better able to discriminate between the various candidates. It is also suggested that the addition of another physician and assistant physician to the medical staff of the hospital would fulfil a want and place them on a numerical equality with their surgical colleagues. The following gentlemen are candidates for the post:—Oswald A. Browne, M.A., M.B. Cantab., M.R.C.P.; Arthur Temple Davies, B.A., M.B. Cantab., M.R.C.P.; A. E. Garrod, M.A., M.B. Oxon., M.R.C.P.: S. H. Habershon, M.A., M.B. Cantab., M.R.C.P.; Vincent D. Harris, M.D., F.R.C.P.; Wilmot P. Herringham, B.A., M.B. Oxon, M.R.C.P.; H. L. Jones, M.A., M.B. Cantab., M.R.C.P.; Percy Kidd, M.A., M.D. Oxon., F.R.C.P.;

J. A. Ormerod, M.A., M.D. Oxon., F.R.C.P.; W. E. Steavenson, M.D. Cantab., M.R.C.P.; Howard H. Tooth, M.A., M.D. Cantab., M.R.C.P.; Samuel West, M.A., M.D. Oxon., F.R.C.P.

A Breach of the Burial Acts.

At an inquest which was recently held at Stoke Gabriel some rather extraordinary facts came to light. A woman, 46 years of age, housekeeper to the Rev. J. H. N. Nevill, suffered for some time from a malady which was diagnosed—without aid from the Faculty—as liver disease, and she died on 18th January. It appeared that no medical man had been called in to attend her, her master, the vicar, aided by the advice of a Mr. Wallace, having usurped the functions of the medical attendant. She was subsequently buried by the vicar without any certificate from the Registrar, and on this coming to the knowledge of the coroner, the body was exhumed, and the post-mortem examination made by Dr. L. J. C. Hains, assisted by Dr. Fraser. Portions of the viscera were sent by these gentlemen to the county analyst for analysis. Evidence was given by a quack called Joseph Wallace, who described himself as a "medical scientist," whatever that may mean. He said that he had seen the deceased, and had found her suffering from "chronic liver disease and a cancerous habit of the body generally," a diagnosis which was in no sense borne out by the post-mortem appearances. He "thanked God" without any adequate reason that he was not a qualified practitioner. Two trained nurses from St. Raphael's Home, Torquay, had been in attendance on the deceased. They do not seem to have seen anything extraordinary in the absence of medical attendance, and one of them was sharply rebuked for expressing an opinion in court that "a doctor would have been no good." It was perhaps no part of their duty to insist on a doctor being called, but they certainly held curious views as to the attributions and functions of "trained nurses." The inquest has been adjourned for the report of the public analyst. Pending his examination no decision can be arrived at as to the cause of death, but we may remark that the liver was not the seat of disease, although two gall-stones were found in the common bile duct, weighing 22 grains. The vicar seems to have been under the impression that he was legally entitled to bury without the legal permit, and he evidently considered that his office authorised him to compound and dispense medicines unaided save by the occasional advice of the London quack. The result of the proceedings may possibly be to enlighten him on one or two points in connection therewith.

A companionship of the "Distinguished Service Order" has been bestowed on Surgeon-Major John Godfrey Rogers, M.B., Medical Staff, for services in the Soudan.

Dr. Symes Thompson commenced the Gresham course of lectures yesterday, at Gresham College, on "The Glands." These will be continued each day this week at six o'clock (Saturday excepted) and are free to the public.

Oxalic Acid in Asthma.

Oxalic acid in two to five grain doses has been much lauded by Dr. Poulet, of Planchet les Mines, in the treatment of essential asthma as well as of emphysematous and bronchitic dyspnœa. He has been using it for five years past, and has never met with any untoward symptoms following its employment, while its effects in relieving the severest dyspnœa has invariably been prompt and certain. Oxalic acid has a strongly sedative action on the heart, and in toxic doses kills by producing cardiac paralysis. It is a powerful antipyretic, and also possesses marked emmenagogue properties. In fever larger doses are tolerated than in health, and it has no cumulative action. It should always be given in a very dilute solution, as otherwise local irritation of the stomach, &c, may result.

Salol in Sciatica.

Dr. v. Aschenbach, of Corfu, reports in the *Fortschrith der Med.* that, suffering from sciatica, for which all known remedies has been tried in vain, he at last resolved to try an unknown one—to himself at least unknown as a remedy for sciatica. In the evening he took a dose of half a gramme, and at midnight one gramme, after which he fell asleep, and remained perfectly free from his pains.

Fractures of the Lower Extremity of the Humerus.

In an elaborate communication on the treatment of fractures of the lower end of the humerus, read before an American society, and printed in the *Boston Medical and Surgical Journal*, Dr. J. S. Bigelow discusses the advantages following the adoption of a mode of treating such injuries in which the employment of passive motion is entirely omitted during union, this kind of manipulation at an early date being condemned as being more often productive of harm than of benefit. Dr. Bigelow writes, moreover, in the most favourable terms of the use of apparatus by means of which the affected arm is put up in a position of extension, and maintained so at complete rest for the term necessary to secure union of the broken fragments; and in defence of this proposal he adduces arguments based on the anatomical distribution of the arm muscles, the effect of which he shows to be, that, when the arm is fixed in the flexed position separation and deformity, and often formation of false joints must ensue at the point of fracture. His own experience of the extension method is confined to four cases, but in every one he was gratified by securing the most perfect result, and he quotes in support of the plan the statement made in its favour by several eminent American surgeons who have all adopted it for some time past as possessing immeasurable superiority over the older and more commonly followed proceedings. The method of using the long straight splint in these cases is similar to that pursued in treating fractured olecranon, and the danger of ankylosis is said not to be in any way a formidable one, while the position assumed by the limb affords the greatest ease to the patient.

Hæmatoma of the Pancreas.

A good deal of attention has been given of late to the study of diseases and injuries affecting the pancreas, an organ of the body which, it must be generally admitted, we have not hitherto been familiar with in its clinical aspect. We adverted some time since to an article by Dr. Senn, of Chicago, in which the question of cirrhosis of the gland was discussed, and on another occasion we hope to deal further with a more recent and general essay by the same author on the "Surgery of the Pancreas," published in the *International Journal of the Medical Sciences*. Of interest in the same connection, however, is the record of a case of hæmatoma of the gland, contained in a recent issue of the *Boston Medical and Surgical Journal*, the subject of the tumour being a healthy labourer who was suddenly seized with nausea, vomiting, and slight diarrhœa, followed a few hours later by pain in the stomach and abdominal cramps, the intensity of which steadily increased. The vomited matter was first green in colour, and subsequently black, but did not contain blood, while the severe and agonising cramp-like pains extended down the thighs and legs, and intense thirst was experienced. Morphine was freely administered by hypodermic injection, but on the fourth day of the attack death occurred unexpectedly. Post-mortem examination revealed a large and hardened pancreas, between which and the duodenum apparently, was a dense discoid tumour, four centimetres in diameter, which presented a hard blackish surface on section. It encroached on the head of the pancreas, and the microscopical structure was clearly that of a hæmatoma.

A Precocious Suicide.

Last week a youth named Stopford, only fourteen years of age, shot himself. In explanation he left behind him a few lines of writing, in which he said he "was gone to meet the great mystery face to face." It would be interesting to know something more of this youngster's moral training and antecedents, together with the family history. The age of puberty is generally an emotional epoch, with boys as well as with girls, and one phase of this emotional period is an extreme depression, sometime amounting to a *nausea vitæ*. It is at about this age that children begin to be brought face to face with the hard facts of life. Death, want, ingratitude, possibly often seen before, then assume a greater reality and become tangible entities. Lads who, from circumstances, training or heredity, are wanting in force of character, are sometimes unable to withstand these periods of depression and become sullen, morose, or decidedly melancholic. As they get older, habit and reason fortify them against such attacks, from which they may remain free until, broken down by ill-health, excesses, or worry, their powers of resistance are so far enfeebled as to open the door to melancholy from which they rally less readily. Lads who suffer from symptoms of this disordered psychical condition, require, as a rule, but food and exercise in order to overcome it. A little hygiene will often work wonders, especially if combined with a change of air. The more serious cases require a careful moral training in experienced hands, otherwise their intellectual powers may suffer even to the extent of extinction. In no case should they be treated with contempt or harshness, since their condition is thereby only intensified.

Seniority of Army Medical Officers.

Dr. Tanner has given notice that he will ask the Secretary of State for War whether officers of the Army Medical Staff, who obtain the greatest number of marks at the competitive examination for commissions in the public services are placed junior and therefore inferior in position to those who, obtaining a fewer number of marks, seek commissions in the other branches of the public services; whether all medical officers are allowed to reckon one year on half-pay in their service, if caused in and by the service, as full-pay towards retirement, and whether, in the case of officers of the Royal Engineers, towards promotion as well as retirement; whether the commissions of gentlemen joining the Indian Medical Service are dated from the period of joining at Netley, and whether those for the Army Medical Department are dated from the period when the course of instruction at Netley closes; and, whether such regulations practically make the Indian medical officers the seniors of the others by four months or more, and if this continues throughout their career until they reach the administrative ranks.

The Carmichael Prize.

We understand that the Irish College of Surgeons has received no less than nine essays in competition for this prize, which is to be awarded next May. The "Carmichael" Prize Fund was founded by the late Richard Carmichael, a former President of the College, who bequeathed £3,000 to the college for the formation of the fund. In 1869, questions having arisen as to the administration of the fund, and as to the reversionary rights of the Royal Medical Benevolent Fund to a share, the matter was brought before the Master of the Rolls, who ordered over £600 to be handed over to the Treasurers of the Benevolent Fund. £2,974 5s. remained in hand after payment of the foregoing sum, and the interest accruing on this sum was ordered to be appropriated to the prize. That every fourth year, premiums not exceeding £200 for the first, and £100 for the second, are adjudged by the Council of the College for the two best essays on:—First—The state of the Medical Profession in its different departments of Physic, Surgery, and Pharmacy, in Great Britian and Ireland, at the time of the writing of these prize essays. Second—The state of the Hospitals and Schools of Medicine, Surgery, and Pharmacy. Third—The state and mode of examination or of testing the qualifications of candidates of the different licensing Colleges or Corporations in Medicine or Pharmacy. Should the College Council not deem any of the essays worthy of a reward, they are authorised to postpone the granting of premiums until the termination of the next four years, when there shall be another competition. The premium may, in their discretion, be doubled, and a sum not exceeding £400 may be awarded for the first, and £200 for the second prize essay. The prize essays are subsequently published to the extent of 700 copies. The last occasion on which the prizes were awarded was in 1879, when twelve essays were submitted. The first prize was awarded to Dr. Walter Rivington, of London, for essay signed "Nil actum reputans si quid supersessett agendum," and second to Dr. Thomas Laffan, of Cashel, for essay signed, "Audax." Considerable difficulty has arisen in the adjudication ot the prize, in consequence of the difficulty of inducing any competent persons to accept the tremendous task of reading all the essays. The judicial authorities refused to allow arbitrators to be paid out of the Prize Fund, and some of the Fellows of the College have offered strenuous opposition to the allocation of the collegiate funds to such purpose, so that it has been necessary to obtain the gratuitous services of competent judges. Considering that the essays occupy about 16 large volumes of manuscript, it is not wonderful that most of those who are capable of forming a just opinion of their merits are unwilling to accept so prodigious a charge.

An Irish Diploma in Sanitation.

We learn that the Council of the Irish College of Surgeons has taken steps towards the founding of a "Diploma in Public Health." The new Medical Act contains a special clause which authorises the registration of such diplomas as one additional qualification of any person already registered. The scheme for the studies and examinations to be required for such diploma is not yet completed by the College, but it will, we hope, be ready to go before the Medical Council at its meeting next week.

Expurgation.

The Irish College of Surgeons has removed from the list of its Licentiates the name of Mr. William Edward Robson, has withdrawn his diploma, and notified the withdrawal to the General Medical Council, with a view to his qualification of L.R.C.S.I. being erased from the Medical Register. Mr. Robson was guilty of a deliberate violation of the College by-laws and of the declaration taken by him when admitted a Licentiate, inasmuch as he engaged in advertising, first as a testimonialist of "Warner's Safe Cure," and afterwards by handbills and newspaper paragraphs. The College called upon him to abstain from these practices, but he refused to give any promise to adhere to his obligation, and he was therefore very properly removed from all connection with the College. We understand that the Irish College of Physicians has taken steps towards a similar proceeding.

A Reply to the Anti-Vaccinators.

The Registrar-General's Quarterly Report for Ireland, issued last Saturday, states that "no fatal case of small-pox has been registered in any of the fifteen districts of Ireland since September, 1883." Three years and a half without a single death from the disease which fifty years ago decimated the population periodically and afflicted them perennially!! And why? Because in Ireland we have nearly 1,000 public vaccinators paid—if not liberally, at least fairly, for watchfulness and activity in quelling small-pox. What result should we have to record in twenty years if the anti-vaccination fanatics had their way?

Assistants at the University of Edinburgh.

It seems probable that the unfortunate and undignified quarrel between Dr. Rutherford and his late assistant, Dr. Ashdown, may lead to the anomalous position of the assistants being taken seriously into consideration with a view to making them independent to some extent of their superiors, so far as their tenure of office is concerned. After the lamentable occurrence which obliged Dr. Ashdown to resign his post, it is incumbent on the University authorities to take such steps as shall remove assistants from their present uncomfortable situation, and make their nomination and dismissal an official concern. Dr. Rutherford's remarks to his students only aggravates the affair so far as that gentleman is concerned. Without a word, or even a promise, of explanation, he claims their sympathy, though it is doubtful whether this can be relied upon. We are pleased to hear that there is every reason to anticipate an inquiry; it is to the interest of everybody concerned, and last, but not least, to the interest of the University to prevent the recurrence of similar scenes, and it is only by rightly distributing the onus of the affair that justice will be done, and repetition or extension forestalled. The local papers have shown a commendable energy in following the matter up which we initiated.

A total of £2,278 has been received as the result of the appeals made in the churches and chapels of Sheffield on Sunday week in aid of the local medical charities. This is an increase of £156 over the amount received at same time last year.

An Order in Council, entitled "The Rabies Order of 1887," has been officially published. It lays down certain fresh regulations in regard to animals found to be affected with rabies, more especially dogs. The order, which will take effect from and after the 28th inst., will not interfere with the operation of the Dogs Act, 1871.

We regret to announce the death of Dr. Edward Brunker, formerly for many years Surgeon to the County Louth Infirmary, Dundalk. Some years ago he retired from practice, and having come to live in Dublin, was elected to a seat in the Council of the Irish College of Surgeons. Dr. Brunker lived to a very advanced age.

◆

France.

[FROM OUR OWN CORRESPONDENT.]

Resumed Debate on Hydrophobia.—At the last meeting of the *Académiè de Medécine* the debate on the treatment of rabies was continued by M. Grancher who protested on the part of M. Pasteur, against the insinuation made in, a previous meeting that M. Pasteur concealed his failures. This he considered very unjust, for the Laboratory of the Rue de l'Ulm published exact statistics every three months, and henceforth M. Pasteur will publish one every month. In concluding, M. Grancher laid on the table the total lists of persons vaccinated, which were found to be 1,929, eighteen of whom died, making 0·93 per cent. of the total. M. Peter brought forward two new cases which succumbed although inoculated. Canine rabies was a convulsive disease while the virus in the rabbit declared itself by paralysis. It seemed therefore natural to expect that each of these forms should engender similar symptoms in man. Formerly, the paralytic form was as rare in man as it was frequent now, and in his mind this frequency coincided with the inoculation of the rabbit rabies. M. Peter declared to the defenders of the doctrine that in the first case of hydrophobia in spite of the vaccination the cause of death was said to be meningitis at first, but afterwards it was admitted that the patient succumbed to rabies. He was ready to express his admiration for the physiological experiences of M. Pasteur but he considered that the application of these experiences to man was not exempt from danger. During the last year thirty persons died from hydrophobia of whom 16 were not inoculated. According to M. Brouardel exactly that number (30) die every year from the malady. Since M. Pasteur applied his new method of treatment (*inoculation intensive*) those deaths increased and he (M. Peter) could not help thinking that the fatality was due to the manner of treatment. M. Vulpian said that he was as enthusiastic as ever, over the *traitement Pasteur* and he considered that reproach made against the eminent physiologist was unfounded. M. Peter replied that he relied on statistics for his opinion, and went so far as to accuse M. Pasteur and his collaborators of involuntary homicide. The method of M. Pasteur was dangerous, capable of giving the rabies to those who submitted to it, and in any case it was insufficient.

The Conseil d'Etat before declaring that the proposed Pasteur Institution was of public utility demanded another inquiry.

Revision of the French Lunacy Laws.—A revision of the Lunacy Laws is being prepared by the Senate and there is no doubt on the necessity of the new clauses. Heretofore, the sequestration of an individual was effected on the certificate of a single doctor and the assent of the administration. By the new law *three* doctors are required to examine the subject and after their certificate, the prefect and procureur of the Republic must be advised, who are to ultimately decide on the lot of the patient. It is possible that the certificate of the three medical men ought to have been considered sufficient, but in any case means cannot be too much insisted upon to secure a full and free inquiry, It has but too often occurred that from sordid motives a person has to be declared insane and shut up in durance vile. Such a case occurred quite lately in Lyons which created a great stir amongst all classes and to it may be ascribed the haste with which the new bill is being pushed. A lady teacher was suddenly pounced upon by three Sisters of Mercy and a man, while she was quietly teaching her class, and carried out in the most summary manner and put in a cab which was waiting at the door, and brought off to a well known private aylum. The next day the papers gave full details and at once it became a politico-religious affair. The conservative journals maintained the insanity of the lady, and the liberal press stongly affirmed the contrary. In the end the latter proved to right. After an examination ordered by the Prefect the lady was liberated, greatly excited on account of her incarceration of about 15 day, and the director of the Institution was dismissed. It turned out that family interests motived the unworthy conduct.

Treatment of Chorea.—The following is recommended by the highest authorities in Paris:—

Valerianate of zinc
Subnitrate of bismuth } grs. xx
Ext. of hyosciam

Divide into 30 pills, 3 to 6 a day.

Scotland.

[From our own Correspondents.]

Edinburgh Hospital for Sick Children.—The annual general meeting of subscribers to the Royal Hospital for Sick Children, Edinburgh, has just been held. The general report was highly satisfactory. The total number of cases treated was 6,930 of which 6,092 were treated at the dispensary, 189 were vaccinated, and 649 were received into the hospital. The mortality list was 74. The hospital is being further utilised as a training school for nurses. During the past year, five probationers completed their term at the hospital. The connection which has been established between the hospital and both the University and the Edinburgh School of Medicine has given the hospital a most important place in the future development of scientific medicine. With a really scientific staff of physicians the possibilities of the Sick Children's Hospital are great.

Reception of Army Sick in the Edinburgh Royal Infirmary.—Pending the building operations which are in progress at the Edinburgh Castle, with the object of making certain restorations of the old edifice, a temporary arrangement has been come to between the military authorities and the Edinburgh Royal Infirmary. In accordance with this, more serious cases of illness will be received by the Infirmary, and treated in the ordinary wards, while less important cases will be cared for at Piershill and Leith Fort.

Death of Dr. Freer, of Govan.—We regret to have to announce the death of Dr. Frederick A. Freer, of Govan, which took place at Uddingston on the 31st ult. Deceased was forty years of age, and was married to Miss Allan, daughter of the late Dr. Allan, Dalmellington, who survives him. He resided for many years in Govan, and was much esteemed by his numerous patients. At the time of his death he was Medical Officer for the Combination Hospital, and President of the Southern Medical Society.

Glasgow Royal Infirmary.—The annual general meeting of the qualified contributors and subscribers to the Glasgow Royal Infirmary was held on the 31st ult., the Honourable Lord Provost King presiding. The report of Dr. Thomas, the Medical Superintendent, showed that, in 1886 the admissions were 4,817, against 4,945 in 1885, showing a slight decrease in numbers. Of these 4,834 were treated to a conclusion, 437 died, giving a mortality (exclusive of those who died within a few hours of admission) of 6·6 per cent., as against 7·5 per cent. in 1885. The cost of each fully occupied bed during the year was £49 9s. 2½d., and the average cost of each patient treated to a conclusion was £4 19s. 5½d.

The Royal Infirmary School of Glasgow as a College of the University.—A memorial of the managers of the Glasgow Royal Infirmary has been presented to the Right Hon. the Secretary for Scotland and the Right Hon. the Lord-Advocate, submitting that, in the forthcoming Universities (Scotland) Bill a clause should be introduced to erect the medical school of the Glasgow Royal Infirmary into a college of Glasgow University. The memorialists contend that the Royal Infirmary of Glasgow is one of the largest hospitals in Great Britain, containing nearly 600 beds, and that it receives more surgical cases than any other hospital in the kingdom. In consequence of certain recent changes, extra-mural medical teaching in Glasgow has declined, and it is certain to suffer still more from the circumstance that the curriculum and examination requirements from intra- and extra-mural students are now all but alike, and from the greater facilities for obtaining degrees in England by the erection of the Newcastle School into a college of Durham University, and the Manchester and Liverpool Schools into colleges of the Victoria University, and from the near prospect of similar advancement in the case of the Birmingham and Leeds Schools, and by the increasing desire among medical students to obtain degrees. They therefore submit that the monopoly of University privilege in Glasgow should no longer be confined to one school in the extreme west of the city, but that the Royal Infirmary Medical School should be erected into a college of the Glasgow University, thus following the precedents of Oxford and Cambridge, and of the Newcastle, Manchester, and Liverpool Schools of Medicine already referred to.

Sanitary Department.

CLEARANCE OF A DUBLIN UNHEALTHY AREA WITHOUT COST TO THE RATEPAYERS.

At the meeting of the Public Health Section of the Academy of Medicine in Ireland, on Thursday last, Sir Charles Cameron, Chief Medical Officer of Health for Dublin, read a remarkable paper on a clearance of an unhealthy area which he had effected without cost to the ratepayers. In the early part of his paper he entered at considerable length into the provisions of the various Acts of Parliament which enabled sanitary authorities to deal with ruinous and insanitary dwellings, and criticised their excessive forms and routine, which hampered unnecessarily the action of the local authorities. For these reasons he found the provisions of the Labourers' and Artisans' Dwellings Acts and the Acts incorporated therewith impracticable so far as they related to the closing or repair of insanitary and ruinous houses. A better Act for this purpose was the Towns Improvement Act of 1847 and the Dublin Local Improvement Acts, which were the result of that general statute. For the clearing of a whole area the Artisans' and Labouring Classes' Dwellings Act could be applied, but in such case it was found that preposterously large compensation was often awarded by juries to the persons whose insanitary houses were cleared away. The Corporation of Dublin had expended in the clearance of the Coombe and Plunkett St. unhealthy areas the sum of £56,700, or allowing for the rent obtained from the acquired ground, at the rate of £5,971 per acre, or about £18 per head of the population removed. Sir Charles Cameron, as Health Officer, proceeded to deal with unhealthy houses under the 107th and 113th sections of the Public Health Act, which Sir Charles says are the simplest and yet most efficacious and practical sanitary measures ever enacted. Under those clauses any premises the magistrate can, on complaint being made of them, order to be detenanted and closed. More than 2,000 such houses have within the last six years been closed more than one-third permanently. Under these provisions Sir Charles Cameron succeeded in getting a whole area, comprising more than an acre, completely cleared without cost to the ratepayers. The area embraced nearly the whole of Wood Street, Arthur's Lane, and Oliver's Alley, and a part of Golden Lane: 39 houses, inhabited by 353 persons, were closed and subsequently pulled down, and are now waste ground, upon which no doubt healthy dwellings will in time be erected. If this area had been cleared under the operations of the Artisans' and Labouring Classes' Dwellings Act, it would have cost at least £6,000.

In Sir Charles Cameron's paper some curious facts were given as to the homes of the poor. From a census which he had taken he found that there were 32,202 of the families residing within the civic districts of the Irish metropolis located in only 7,234 houses, whilst the remaining 22,523 families occupied 16,977 houses. The former 7,234 houses contained 48,116 rooms, or at the rate of 1½ families per room. Sir Charles ascertained that four streets, Jervis Street, Church Street, Upper Mercer Street, and North Cumberland Street, contained 175 houses in which there were 1,482. The houses, all let to weekly tenants, realised £8,311 13s. a year, although their valuation for taxing purposes was only £2,677 10s. One house, valued at £8 per annum, was rented at £52 to weekly tenants.

At the Societies.

PATHOLOGICAL SOCIETY.

The opening paper read at the last meeting of the Pathological Society of London described several examples of diseases of the genito-urinary organs in animals confined in the Zoological Gardens. This contribution is a continuation of the series of observations in this connection recorded by its author, Mr. Bland Sutton, and the interest of the communication is in nowise inferior to that of those which have preceded it. The cases instanced included one of renal calculi in a sloth, distension of the vaginal, cervical, and uterine cavity in a deer, and retained placenta in an agouti. Sir James Paget, commenting on these and other instances of disease in animals cited by Mr. Sutton, remarked on the invaluable character of Mr. Sutton's work, and put the question if the diseases of recently imported animals differed much from those found in animals long resident in the Zoological Gardens. In reply, Mr. Sutton made the important statement that it was the first twelve months that settled the question whether an animal would be much affected by disease or become ultimately acclimatised.

An interesting essay was next read by Mr. D'Arcy Power, on the pathology of Colles' fracture, the conclusion of which was to the effect that the usual form of this accident is really an example of comminuted fracture. The two classes of cases, however, are clinically indistinguishable, and favourable results follow treatment in both; and it was pointed out that probably the great majority of ordinary fractures of the lower end of the radius are of the character explained.

Dr. Griffiths followed with an account of early pregnancy in the fimbriated extremity of a Fallopian tube, with a large extra-uterine hæmatocele, the specimen in question being exhibited. Dr. Griffiths urged the belief that, notwithstanding recent controversy, effusions of blood in this region are true intra-peritoneal hæmatoceles, and that the hæmatomata of Mr. Lawson Tait and others are principally a new disease resulting from operative interference with the broad ligaments.

A specimen of ruptured bladder formed the subject of a communication from Mr. Bruce Clarke, the man from whom it was taken having been run over at seventy-five years old. There was stricture of the urethra, and, as pointed out by Sir James Paget, the muscular coat of the bladder was much thickened. The paper was discussed at some length by Messrs. Rivington, E. H. Fenwick, and Godlee also, and was followed by an account of a tubercular brain tumour from a boy, Mr. Gilbert Barling recording the case. In reply to questions put by Drs. Owles and Norman Moore, it was stated that no evidence was found of scrofulous disease in the kidney, or of tubercle in any other part of the body.

A long discussion next ensued in connection with a specimen comprising the vault of a cranium perforated in four places as the result of tubercular disease of the bone, and the meeting was concluded by consideration of a specimen of horny papilloma of the hand in a woman of 75, shown by Dr. Edmunds.

MEDICAL SOCIETY OF LONDON—Monday, Feb. 7th.

Mr. Edmund Owen read the notes of a case of Littre's hernia which he proposed to call partial enterocele. The peculiar features of this form of hernia consist in the continued action of the bowels, the mildness of the constitutional symptoms and the establishment of a fæcal fistula. The patient was a man, 57 years of age, who had a general hernia on the left side with symptoms of strangulation. As nothing called for immediate intervention, ice was applied. The symptoms of strangulation disappeared, but an abscess formed, which, on incision, gave exit to pus and fæcal matter. The diagnosis was that of partial strangulation and gangrene of the gut, probably the ileum—by a diverticulum or otherwise. Mr. Frederick Treves expressed doubts as to the correctness of the diagnosis and suggested that the continued application of ice might have tended to the formation of the abscess.

Mr. Stephen Paget read a very exhaustive paper, bristling with figures and statistics, on the supervention of parotitis after injury or disease of the abdomen or pelvis. There are several ways of accounting for its advent, as Mr. Alban Doran pointed out, but neither of them is altogether satisfactory, and Mr. Paget suggested that they might not all be due to the same mechanism.

Mr. Hugh Smith gave the history, and showed the specimens from a case of aneurism of the third portion of the aorta which ruptured into the pericardium, and caused immediate death. Rupture into the pericardium is rare in aneurism of the third portion, but in this case it had contracted adhesions.

PATHOLOGY IN DUBLIN.

At the meeting of the Dublin Branch of the British Medical Association a resolution moved by Mr. Thomson and seconded by Professor Cunningham was unanimously passed, remitting to the Council to take such steps as may be necessary to bring before the various teaching bodies in Dublin, the necessity of providing systematic instruction in pathology. Without stopping to inquire whether a question of medical curriculum is any part of the legitimate business of a medico-political organisation like the Branch, we may, without hesitation, concur in the proposition that Dublin is lamentably in arrear in the teaching of pathology, there being only one genuine course of instruction, that of Professor Purser, given in Dublin on the subject. It is indispensable that the Dublin School shall be reinforced by systematic teaching on the subject, and we hope the schools and colleges may be able to make provision for it. But we hope, nevertheless, that the occasion will not be utilised to impose another three-guinea course of lectures on the overburthened student. Already his pocket is drained and his working time over-burthened with such instruction, and the Irish diplomas are weighted with an excessively expensive curriculum. If pathology is to be added, some less useful course must be subtracted.

BANQUET OF THE FRENCH HOSPITAL.

The nineteenth annual banquet on behalf of the above institution took place on Saturday last at Willis's Rooms, the Comte d'Aubigny, *vice* the French Ambassador, in the chair, supported by the Lord Mayor. There was, as usual, a very good attendance, and the usual toasts were drunk. Allusion was made by the Lord Mayor to the desirability of preserving cordial relations between the two countries. M. Eugene Rimmel, the honorary secretary of the hospital, was unfortunately incapacitated by illness from attending, and very general regrets were expressed at his absence with hopes for his prompt recovery.

AMALGAMATION OF IRISH UNIONS.

We note that the shrinkage of indoor pauperism which has followed upon the extension of outdoor relief, and has already caused the Newport Union to be merged in that of Westport, and has swallowed up the Donaghmore Union, is likely now to produce amalgamation in other districts. Last week the Local Government Board Commissioners held a public inquiry at Ballina, the object of which was the advisability of amalgamating Ballina, Belmullet, and Killala Unions. The medical officers of the workhouses of these unions ought to recollect that, if their offices are abolished by this concentration of unions, they are entirely at the mercy of the guardians for superannuation. When the Newport Union ceased to exist the workhouse officers were turned out without a shilling, and they had no redress.

We understand that Surgeon-General McDowell, of the Army Medical Staff, has been selected for the important post of Principal Medical Officer at Halifax, Nova Scotia.

At the presentation of prizes at Netley on Monday, Sir J. Fayrer announced that Dr. Waring, late of the Madras Medical Service, had bequeathed his magnificent library to the Medical School. This collection of works on Materia Medica is said to be one of the finest extant.

The University of Berlin has this winter 5,357 students, the largest number ever attained by a German University. There are 2,230 first year's men, and 1,164 men who have gone away on completion of studies. Of the total number 1,297 are students in medicine.

Correspondence.

THE "JACOB TESTIMONIAL."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I am glad to see by the lists published weekly in the medical journals that the "Jacob Testimonial" promises to be a great success, and is supported by all grades of the profession, both in England and Ireland from the practitioners in the poorest provincial districts in Ireland, to the leading consultants in the profession in London and Dublin, which is sufficient evidence to show that the service of Dr. Jacob to the profession is fully recognised. But while it is gratifying to the promoters of the Testimonial, that their object is thus shown to be deserving, it is to be regretted that the list does not include every man without exception in the Poor-law Service in Ireland, who owe so much to Dr. Jacob for his never-ceasing efforts in their behalf. Dr. Jacob has been rightly designated by a writer the "Champion of the Dispensary Doctor."

I am, Sir, yours, &c.,
A Subscriber.

FRACTURE OF BOTH CLAVICLES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The following account of this rare accident may be of interest to your readers:—

B. M., coachman, æt. 60, was admitted into the Kells Hospital on the 20th September. A few hours before his admission he had gone alone into a loose box stall to attend a young mare that had been fired a few days previously. On passing round behind her, the mare backed so rapidly upon him, that she caught him between the wall and her hind quarters, pinning him with his right shoulder against the wall, and his left shoulder against her hind quarters.

While crushing him violently in this position, the mare tried to kick, but fortunately for B. M., she was so closely pressed against him that she could not lash out, and her attempts to kick only resulted in upward heaves of her hind quarters. These upward heaves lifted B. M. off his feet, and he states that, though he felt terribly crushed while the mare steadily pressed him against the wall, it was only on her trying to kick that he felt his collar bones snap, which they did under the additional sudden upward jerking pressure. His cries at last were heard, and he was rescued from his perilous position and brought to hospital. On admission, I found him suffering from severe shock and in great pain, the right shoulder greatly bruised, and both clavicles fractured, the outer fragments being greatly displaced. The treatment I adopted was most successful, both as to the rapid relief of the distressing symptoms and the ultimate perfect recovery of the patient.

I slipped a large, soft, but firmly padded ring over each arm, and pressed it well home into each axilla, secured the rings steadily together with a Martin rubber bandage, crossed the hands over the chest, and secured them and the upper arms firmly with long strips of Seabury's rubber plaster, placed the patient flat on his back, and kept him so for ten days. Notwithstanding his perfectly helpless condition he made most satisfactory progress, and was discharged with firm bony union of both fractures, and muscular power and motion perfect in both arms.

I am, Sir, yours, &c.,

Kells, Co. Meath, Feb. 1, 1887. John Ringwood.

◆

"VACCINIA AND VARIOLA."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—One cannot help seconding the suggestion made by "M.D." in this week's *Medical Press*. A few weeks ago, in a letter to the *Lancet*, I endeavoured to combat Mr. Fleming's objections as to the identity of these two diseases. So far he has not contested my arguments, but I am far from hoping that he has considered them conclusive. But were he (as with his peculiar advantages he might do) to undertake a prolonged series of experiments in inoculating heifers or calves with the virus of small-pox, *in presence of an impartial committee*, the question of the identity of variola and vaccinia—if question it still be—might once and for ever be transferred from the realm of discussion to the region of fact.

I am, Sir, yours, &c.,
Arthur Harries.

MERCER'S HOSPITAL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In your issue to-day, under the heading "Notes on Current Topics," you speak of the decadence of Mercer's Hospital during the last three years.

I fail to see what grounds you have for making this sweeping assertion to your readers, in the face of the following facts, which any one of them can without trouble ascertain for himself.

During the last three years—1. The Board of Management has been enlarged. 2. Patients are admitted in a regular and proper manner. 3. Its officers are supported in the exercise of their duties. 4. The Hospital has been freed from debt; at the present moment it does not owe one shilling. 5. The Building Fund has increased from one thousand to five thousand pounds. 6. The patients are comfortable, and steadily increasing in numbers; over 30,000 treated last year. 7. The Hospital is clean and nursing good.

I leave your readers to form their own conclusions as to the source of these unworthy attacks on a charity which is rapidly completing a period of usefulness extending over two centuries.

I am, Sir, yours, &c.,
Charles Frederick Knight, M.D.

Feb. 2nd, 1887.

Literature.

SUTTON'S MEDICAL PATHOLOGY. (a)

The authority of Dr. Sutton's name must at once assure a respectful attitude towards any work proceeding from his pen, but the feeling awakened by a perusal of these lectures passes rapidly from respect to admiration, and we rise from their study not only conscious of an increase in our knowledge of disease, but impressed with the conviction that we have acquired an insight into the philosophy of the subject such as it is the rarest possible gift of teachers to impart. The character of the work is throughout that of the man who is responsible for it; and those who have enjoyed the advantage of listening to its author's often profound reflections on disease and its causes, will at once welcome in the lectures now given to the world, a faithful reproduction of the sententious and, to use a favourite term of Dr. Sutton's, rhythmical views which distinguish him as a thinker. The language is often of the most picturesque description, but the truth to be conveyed is always presented in the most obtrusive possible fashion, so that who will not learn it are alone to blame for ignorance. The scope of the work does not do more than cover the ground of a general introduction to medical pathology; but every generalisation is emphasised by the results of the author's unusually large experience; and the application of principles is so skilfully carried out that each fact, as it is unfolded is impressed upon the mind of the reader in a hitherto unappreciated light, and with the effect of enlarging his conceptions of the processes concerned in the production of diseased conditions. Without resorting to quotations precluded within the limits of a review, it is impossible to convey an adequate idea of the peculiarly impressive style which the author adopts in conveying the lessons he has to impart. Perhaps the chief charm noticeable in this connectionis the strain of deep philosophical reflection which distinguishes the book throughout, and which those who have enjoyed the advantages of hearing Dr. Sutton in the lecture-room will at once recognise as a prominent feature in his discourses. The terse, nervous sentences are typical of the spoken speech, and here we have them reproduced with almost the force they affect when actually received by the ear. Small as the dimensions of the book are, it contains innumerable phrases, sentences, and even paragraphs, which many will learn and employ as guides to practice. A single instance will suffice to show this, and we take from p. 7 the following acute and suggestive criticism of the prevalent contending views explanatory of the changes in the vessels during inflammation. "To account for these changes, some have said that there may be a spasm excited in the wall of a small artery, due to disturbance of nervous power; and that this spasm is followed by paralysis of the wall of the vessel, and excessive distension. Others have said 'No; there is not always spasm;' there may be other disturbance of nervous power in the vessel that is so paralysed. There is a basis of truth in both views, but both fail to take into account this condition, that the contents of the vessels, and the plasma about the vessels continually and evenly work together; and so long as they do this there is healthy nutrition. Therefore, in inflammation there is some failure of normal attraction between the blood and the plasma of the tissues outside the blood-vessels, and the blood and the plasma cannot cooperate as in health." It would be easy to multiply examples of this kind from a volume which is full to richness with them, and which is from cover to cover attractive in the extreme. It comprises twenty-two chapters in all. The subjects treated are arranged in the order in which they formed the heads of lectures delivered during 1885 to students of the London Hospital. These on chronic bronchitis and heart disease are luminous expositions of the difficult problems involved in the study of these diseases; but it is impossible to say that any part of the book exceeds the rest either in the lucidity and suggestiveness of its explanations, or in the beauty of the language employed to convey the author's meaning. The work is a most important contribution to our scientific literature, for all it is presented with so much characteristic and unassuming modesty. The publishers have done their work well, the paper and printing being excellent, and the binding very tasteful. The long list of *corrigenda*, however, indicate defective proof reading, which, in the next edition will, we trust, be conspicuously absent.

◆

MURRELL ON MASSAGE. (*a*)

Massage must now be regarded as an important addition to the physician's *armamentarium*. The writings of Metzger and of Van Mosengeil, of Weir Mitchell, and of Playfair have given it a scientific basis, and have secured to it an accredited place in therapeutics. It is, therefore, expedient that the practitioner should be possessed of a readily accessible guide to its methods of application. This Dr. Murrell has provided.

After a rapid historical sketch, Dr. Murrell briefly but clearly explains what massage is and what it is not. He wisely emphasises the necessity of really practising massage when one professes to do so. Satisfactory results may only be reached by a rigid adherence to the authorised system. Discredit and disappointment are the sure consequences of a loose and irregular method. By a perusal of Dr. Murrell's work the physician will understand to what he is asking his patient to submit.

◆

THE PHYSICIAN'S VISITING LIST.

The *vade-mecum* for the practitioner's pocket which Messrs. Smith, of Long Acre, have issued for 1887 is the most recent of a valuable series of many years, in which the maximum of convenience and adaptability is combined with the minimum of cost and bulk. It does not seem as if anything better could be devised for its purpose, and apparently the professional public is of our opinion, for the demand for it has been sustained through many years.

◆

RUSSELL ON MORBID CARDIAC CONDITIONS. (*b*)

Much of recent writing on the subject of the heart has partaken of the *résumé* character, and one rises from the perusal, wearied but dissatisfied. In Dr. Russell's modest volume of investigations we have to welcome a contribution of real value and great interest. In six chapters he discourses, in a thoroughly scientific manner, several of the more recondite topics of cardiac pathology. In the first he gives a rapid but careful survey of the shifting views which have been expressed regarding inorganic murmurs. Perhaps more recent German work might have received fuller consideration. In the second chapter, he treats of the condition of the heart in debility, and its relations to the thoracic wall. Here, and throughout the volume, Dr. Russell gives especial prominence to the right side of the heart as the immediate cause of certain phenomena, which, he holds, have hitherto received insufficient explanation, more particularly the varying degrees of pulsation which are met with to the left of the sternum, and are yet separable from the apical beat. While thus magnifying the immediate importance of the right heart as the efficient factor, the author never loses sight of the ultimate importance of the left ventricle. He skilfully pilots the student from point to point in the vicious circle, and logically maintains his ground. The third chapter deals with the site and mechanism of the cardiac murmurs in debility and anæmia. Here, again, Dr. Russell does some special pleading for the right side of the heart and the pulmonary artery, finding fault with those who, apart from anatomical or other sufficient grounds, have ascribed the seat of certain murmurs to the left auricle and its appendage. In the fourth chapter he speaks of the vascular murmurs in chlorosis and anæmia, and in Chapter V, of some points connected with tricuspid murmur and mitral stenosis. The volume closes with an interesting discussion of the differential diagnosis of vegetative or verrucose endocarditis. Dr. Russell is of opinion that cases of this kind may be made out with far greater certainty than is usually supposed. He lays especial stress on continued elevation of temperature and increased pulse-rate, a condition of inexplicable irritability, and the presence of albumen in the urine, when such symptoms occur in a patient in whom the general appearance and physical signs point to cardiac mischief. Altogether the volume of essays shows its author to be at once a keen and exact observer, and an inductive reasoner of power and individuality.

◆

THE MODERN TREATMENT OF STONE IN THE BLADDER BY LITHOLAPAXY. (*a*)

Influenced by the rapidity with which a pamphlet of his on this subject was taken up on the spot as well as by by the fact that he had, at the date of its issue, or soon afterwards, completed 128 cases of this kind, Dr. Freyer thinks that he is not only justified, but actually called upon to issue this monograph. We think so too, and we heartily congratulate him on the condition, well nigh perfect, to which he has brought this procedure. But then he had to his hand one of the best, if it is not, indeed, the very best of its kind in the world, and "the extreme aversion with which the natives of India regard any method of treatment that involves several distinct surgical proceedings extended over an indefinite period is well known to every surgeon who has practised in this country." Such is, indeed, the truth, and a performance by which, as he alleges, he has reduced the mortality of calculous operations in India from 13 per cent. to 5¾ per cent. is assuredly worthy of study and acceptance at the hands of lithotomists or litholapaxists all the world over.

For the details of the operation, which are given at length in this monograph, which further contains several illustrations that are obviously taken from one or other of the surgical instrument makers' catalogues of the day, we must refer our readers to the book itself, and we need only add that Dr. Freyer writes in an easy offhand style, that the type is good, and that it contains several valuable hints and tables bearing on this disease, its detection, or general medical and operative treatment. Our author is also, in his way, a bit of a discoverer, and this little discovery of his was, like so many other much larger ones, brought about by an accident. Dr. Freyer one day pumped some water into the bladder of a Hindu, which he had previously searched in vain for a stone, and then introduced "a No. No. 14 catheter and applied the aspirator." After going through this process, and while exhausting the contents of this viscus with an aspirator in the ordinary way, a distinct click was heard during the exhaustion of the water, due to the caculus being carried with force against the eye of the canula by the outgoing stream, and *voilà tout*, this is our author's discovery! We fancy we have somewhere heard of it before. But *n'importe*, there it is, "as large as life and twice as handsome," and it has at least the advantage of being safe and easily employed.

For the rest, and, as our readers look more for results than for fanciful discoveries or elaborate statistics, we will let them have these in their author's own words:—"In my own practice (says this gentleman) I have performed 321 operations for stone in the bladder. Amongst these were 171 adult males and 1 adult female, 143 male and 6 female children. Litholapaxy was performed in 125 adults with 5 deaths, and on 3 female children with no death. . . . There were 47 adult males treated with lithotomy with 9 deaths. In the 143 cases of stone in male children, lateral lithotomy was the operation performed on all, *and amongst these there was no death.* There were, therefore, 125 adults treated by litholapaxy with 5 deaths, or 4 per cent., against 47 adults treated by lithotomy with 9 deaths, or about 19 per cent." But our author holds that this was not a fair comparison, as, since the introduction of litholapaxy into his practice, "only cases unsuitable for this operation were treated by lithotomy." He claims, in a word, that he has, by means of this operation, diminished or reduced the mortality of this procedure, as above, from 13 to 5¾ per cent., and he rightly concludes that the universal adoption of the former operative measure is likely to be attended in India and out of it by a vast diminution of the mortality of calculous operations.

TRANSACTIONS OF THE ACADEMY OF MEDICINE IN IRELAND (a).

The fourth volume of the Transactions fully maintains the eulogiums gained by the preceding volumes, and evinces the care exercised in its compilation.

It is satisfactory to find that the Academy continues numerically and financially sound, though a matter of regret that the student associates are so few, the proceedings at the various sections being invaluable to senior students.

In the Medical Section, Dr. J. W. Moore's case of True Relapse in Enteric Fever, is of much interest, showing that the contagium having expended its initial force, left behind pabulum for renewed manifestations in the same patient; this may explain how it is that the exanthemata occasionally attack the same individual more than once; the shorter duration of the second attack and the diminished severity show that a certain amount of immunity had been conferred by the first attack.

A case of Partial Embolism of the Central Artery of the Retina, by Dr. A. H. Benson, is of interest as bearing on the pathology of chorea.

A timely paper on the Therapeutic Uses of Digestive Ferments, by Professor Purser, warns the practitioner against the hasty and indiscriminate use of digestive aids.

A masterly scientific exposition of the Cardiac Murmurs of the Mitral Area was given by Dr. C. J. Nixon, which has enriched the literature of the subject.

Dr. Cruise contributes a paper on the Quantitative Estimation of Albumen, Urea, and Sugar in Urine, giving the busy practitioner ready and accurate methods of procedure.

Dr. Finny contributes Clinical Notes on a case of Acute Lichen Planus. Dr. Little, a case of Enteric Fever with unusual symptoms and morbid appearances.

In the Surgical Section —Mr. Kendal Franks adds to the Science of Surgery in his paper on the Advantages of the Principle of Dry Dressings in Antiseptic Surgery, and opens up the question in another communication on the Nature of Scrofulous Glands in the Neck, and their Surgical Treatment.

A unique case in the records of surgery appears from the pen of Mr. Wheeler, on Pharyngocele and Dilatation of Pharynx, with existing diverticulum at lower portion of Pharynx, being posterior to the œsophagus; cured by Pharyngotomy.

Mr. W. Thornley Stoker contributes a paper on Bone Drainage in Hip-Joint Disease; and Sir William Stokes in another contribution on the same subject advocates the value of employing this method in the early stages of Hip Disease.

Mr. Hayes brings forward cases of Electrolysis for the Treatment of Urethral Stricture, showing some good results, but this method of treating strictures is yet in its infancy in Ireland, and is not so frequently resorted to as in America.

In the Obstetrical Section—Dr. W. C. Neville has devised a very ingenious Axis-traction Forceps, its advantages being those of a double-curved forceps; the traction apparatus can be fitted to any ordinary double-curved forceps, and the forceps may be used without the traction apparatus. Dr. More Madden draws attention to certain displacements of the Ovaries; also to the treatment of Chronic Cystitis in Women, a subject which has attracted considerable attention of late. Dr. W. J. Smyly advocates the use of the curette in the Diagnosis and Treatment of Diseases of the Uterine Mucous Membrane; the method advocated appears to be reasonable, and one likely to lead to the happiest results.

In the Pathological Section —Dr. Foot showed specimens from a case of Bright's disease, in which the difficulty in diagnosing existing, pericarditis was very marked. Dr. Finny, a rare termination of Ulcer of the Stomach. An interesting case of Malignant Endocarditis was brought forward by Professor Purser. Dr. Walter G. Smith, a case of Ulcerative Endocarditis limited to the right side of the heart. Dr. C. J. Nixon, Endocarditis with Localised Pericarditis.

In the Section of State Medicine:—Dr. A. H. Jacob discusses the Working of the Contagious Diseases Acts at considerable length he shows the benefits conferred on the Army, Navy, and Civil Population from these acts when in force, the wise provisions of the Legislature for reducing to a minimum the chance of any unjust suspicions or charges being made against any female, and the great unjustice which has been done to the nation by the repeal of these Acts. Venereal disease must for the present advance with rapid strides.

Medical News and Pass Lists.

THE DUBLIN BRANCH OF THE BRITISH MEDICAL ASSOCIATION.

The annual meeting of the Branch was held in the Irish College of Physicians on the 27th ult., Professor Bennett, President of the Branch, in the chair. There was a good attendance, including the Presidents of the Colleges, Sir B. Walter Foster, Sir George H. Porter, Sir Charles Cameron, Dr. Kidd, the Registrar-General, Rev. Dr. Haughton, &c. The Council reported that the number of members (182) shows signs of a progressive prosperity. On the question of the formation of a special fund for the defence of members of the Association against whom legal proceedings might chance to be taken, the Council arrived at the opinion that the formation of a special fund for the defence of members of the Association against legal proceedings is inadvisable, and with reference to the payment by the Association of the travelling expenses of the representatives of the Branches attending the meetings of the General Council the following resolution was adopted:—"That the question of payment of the representatives of the branches having been frequently under the notice of the Council of Dublin Branch, as well of the branch itself, and it having been constantly decided that it is advisable to leave the payment of such expenses to the several branches, the existing Council sees no reason for now altering so carefully considered an opinion." The report then directed attention to the steps taken to have removed a grievance of Irish graduates and licentiates practising in England, due to a regulation of the English Local Government Board, that "any practitioner desiring to act as a public vaccinator in England must produce a certificate of having been instructed in vaccination at one of the educational vaccination stations for England." The Council have the satisfaction of now reporting that the grievance has been acknowledged, and, so far as is consistent with the existing law, removed, by the recent action of the Local Government Board appointing Dr. Montgomery, Secretary Vaccine Department, L.G.B., Ireland, to "give certificates." The Registrar-General for Ireland, Dr. Grimshaw, was elected President of the Branch for the ensuing year. Dr. Grimshaw then delivered an inaugural address, "On the State in relation to the Medical Profession." Dr. William Thomson moved: "That the Council be requested to take such steps as may be necessary to bring before the various teaching bodies of Dublin the necessity of providing suitable instruction in pathology." Professor Cunningham seconded the resolution, which was supported by Dr. Kidd, and unanimously passed. In the evening the annual dinner was held in the hall of the King and Queen's College of Physicians, Dr. Grimshaw presiding. Among those present were Lord James Butler; Sir Redvers Buller, V.C., Under-Secretary for Ireland; Judge Boyd; and other distinguished persons.

Sanitary Registration of Buildings Bill.—A special meeting of the Council of the Sanitary Assurance Association was held on Monday last for the final revision of the above bill before presentation to the House of Commons, Sir Joseph Fayrer, K.C.S.I., F.R.S., in the chair. The new measure was adopted by the Council, and in the absence of Dr. Farquharson, M.P., from England, it was decided to ask Mr. C. C. Lacaita, M.P., to take charge of the bill in the House of Commons. The bill as introduced in 1886 consisted of ten sections, and, it will be remembered, made the sanitary registration of all buildings compulsory in towns of 50,000 inhabitants and upwards. The new bill consists of seventeen sections, and is to apply to all towns or districts of 2,000 inhabitants, but it is only to be compulsory in the case of schools, colleges, hospitals, asylums, hotels, and lodging houses. An important feature of the new bill is that the local authorities will have to keep a sanitary register in which any building certified in accordance with the proposed Act may be registered, so that a stranger visiting any district would be able to ascertain at the office of the local authority whether any particular house was or was not certified as in a satisfactory sanitary condition. The new bill will no doubt be more acceptable to sanitary experts, seeing that all persons entitled to certify must first obtain a licence from the Local Government Board, and provision is made for the appointment of examining boards. Persons entitled to sign certificates are designated Licentiates in Sanitary Practice.

The New Government Order on Rabies.—The Official *Gazette* of Friday last publishes an Order in Council, made on Jan. 31st, in substitution of the Rabies Order of last year. The following are the special regulations of local authority as to dogs:—Any local authority may make, from time to time, such regulations as they think fit for the following purposes, or any of them:—(*a.*) For providing for the muzzling of dogs except when securely attached to or kept within a kennel, stable, house, building, or other like place. (*b.*) For providing for the keeping of dogs under control (otherwise than by muzzling) by the owner or person in charge thereof, in such manner as may be prescribed by such regulations. (*c.*) For providing for the seizure and detention of stray dogs or of dogs not muzzled or of dogs not being kept under control in the manner prescribed by such regulations, and for the recovery by the local authority of the expenses incurred by them in respect of the detention of any such dogs from the owners thereof. (*d.*) For providing for the seizure, detention, and disposal, including slaughter, of dogs being at large and affected with or suspected of rabies, or being or having been in the same kennel, stable, house, building, or other place, or in the same pack, or otherwise in contact, with dogs affected with rabies or being or having been otherwise exposed to the infection thereof. (*e.*) For prohibiting or regulating the holding of shows or exhibitions of dogs, and the exposing of dogs for exhibition or sale thereat.

Vital Statistics.—The deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 21·1 per 1,000 of their population, and were—Birkenhead 14, Birmingham 20, Blackburn 26, Bolton 19, Bradford 19, Brighton 17, Bristol 30, Cardiff 25, Derby 11, Dublin 28, Edinburgh 18, Glasgow 29, Halifax 23, Huddersfield 21, Hull 19, Leeds 23, Leicester 19, Liverpool 26, London 19, Manchester 27, Newcastle-on-Tyne 25, Norwich 24, Nottingham 19, Oldham 22, Plymouth 24, Portsmouth 22, Preston 23, Salford 16, Sheffield 19, Sunderland 22, Wolverhampton 17. The highest annual death-rates in these towns last week were—From measles, 1·9 in Hull, 2·1 in Bristol, 2·9 in Leeds, and 3·5 in Huddersfield; from whooping-cough, 1·3 in Halifax, and 1·7 in Huddersfield; and from scarlet fever, 1·0 in Sheffield and in Preston, and 1·4 in Salford. The 40 deaths from diphtheria included 22 in London, 5 in Glasgow, 3 in Manchester, and 2 in Edinburgh. Small-pox caused no death throughout the United Kingdom.

Royal Colleges of Physicians and Surgeons, Edinburgh, and Faculty of Physicians and Surgeons, Glasgow.—The triple qualification examinations were held in Edinburgh in January, with the following results. The following candidates having passed the final examinations at the January sittings of the Court, were admitted L.R.C.P. Edinburgh, L.R.C.S. Edinburgh, and L.F.P. and S. Glasgow:—

Browne, Samuel T., Madras
Calderwood, John A., Ayrshire
Carlyle, J. Cochrane, Toronto
Chepmell, Charles V. J., Paris
Coatsworth, Richard, Toronto
Daniel, Ronald A., Wexford
Darbyshire, James, Denbigh
Dickson, William F., Old Cumnock
Douglas, Francis H., Donaghadee
Edward, Vincent, East Indies
French, Albert R., Bandon
Garrett, William F., Penzance
Gordon, Herbert L., Calcutta
Hannon, Michael M., Co. Clare
Hay, John, Wishaw
Hayes, H. W. McCaully, Bangalore
Hogan, Eugene F., Co. Clare
Homfray, Francis A., Gainford
Hughes, Hugh C., Carnarvon
Hughes, Hugh O., Merioneth
Karney, William H., Madras
Kavanagh, E. Raphael, London
Mandell, Frederick, Cologne
Merrison, J. Graham, Ontario
Mills, Arthur T., Wolverhampton
McEvoy, William G., India
Nelly, John Francis, Gort
Norman, L. S. F De Rohan, India
Pinto, Joseph O., Bombay
Primrose, Fredk., Nova Scotia
Reid, James, Tillicoultry
Ryan, Edmond, Co. Limerick
Stewart, Charles D., Clackmannanshire
Sweetnam, Frank A., Cork
Swindell, John L., Surbiton
Tiplady, William, Durham
Wilson, James A. K., North Gower

A large number of candidates also passed their Primary and Second Examinations; these names will be published as usual on their entrance into the profession.

Royal College of Surgeons of England.—The following candidates, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the court of Examiners on Jan. 25th:—

Belson, G. de Veulle, L.R.C.P. Lond.
Brodie, Frederick Carden, L.S.A.
Calvert, John T., L.R.C.P. Lond.
Calvert, W. D., L.R.C.P. Lond.
Holloway, S. F., L.R.C.P. Lond.
Joly, A. M., L.R.C.P. Lond.
Jones, John A., L.R.C.P. Lond.
Key, David Thomas, L.S.A.
Mann, Harold E., L.R.C.P. Lond
Parry, Thomas F., L.K.Q.C.P.I.
Sidebottom, R. B., L.R.C.P. Lond.
Slater, William A., L.S.A.
Vidler, Albert E, L.S.A.
Wheeler, H. J., L.R.C.P. Lond.

The following were admitted on Jan. 26th:—

Barr, G. A., L.R.C.P. Lond.
Barton, E. A., L.R.C.P., Lond.
Bindley, Robert Alfred
Carvalho, Alberto Pedro de, L.S.A
Copeman, S. A. M., M.B.Cantab.
Debenham, H. A., L.R.C.P. Lond.
Haslip, G. E., L.R.C.P. Lond.
Husbands, H. W, L.R.C.P. Lond.
Jarvis, W. C., L.S.A.
Jeaffreson, J. L., L.R.C.P. Lond.
Lyle, C. C. V., L.R.C.P. Lond.
Malpas, James, L.R.C.P. Lond.
Martin, S. G. S. G., L.R.C.P. Lond.
Morgan, W. V., L.R.C.P. Lond.
Norton, Henry Harvey
Smith, Percival, L.S.A.

The following were admitted on Jan. 27th:—

Carey, Basil de Beauvoir, L.S.A.
Cosens, W. B., L.R.C.P. Lond.
Cox, W. J. R., L.R.C.P. Lond.
Davey, Thomas G., L.S.A.
England, G. F. A., L.S.A.
Gilpin, William J., L.S.A.
Going, Joseph A., L.S.A.
Hawkins, Herbert P., L.S.A.
Iredale, T., L.R.C.P. Lond.
Lewis, John Nicholls, L.S.A.
Macnab, Allan J., L.R.C.P. Lond.
Oldham, Montague W., L.S.A.
Ord, George W., L.R.C.P. Lond.
Phillips, Thomas, L.S.A.
Pridham, William F., L.S.A.
Quiller, C. T., L.R.C.P. Lond.
Rusher, John Golby, L.S.A.
Sansom, H. A., L.R.C.P. Lond.
Sen, C. C., L.R.C.P. Lond.
Walker, A. W. H., L.R.C.P. Lond.
Wilson, A. Harvey, M.D.
Wreford, John, L.R.C.P. Lond.

The following were admitted on Jan. 28th:—

Hill, C. M., L.R.C.P. Lond.
Oliver, Charles Pye, L.S.A.
Ormerod, Edward Booth, L.S.A.
Peake, Harold S., L.R.C.P. Lond.
Powell, Edgar E., L.R.C.P. Lond.
Wilde, Leonard, L.S.A.

Netley Medical School.—The Winter Session at Netley Medical School closed Feb. 7th, when the prizes were presented by Sir Donald M. Stewart, Bart., late Commander in Chief of the forces in India, in the presence of a brilliant assemblage. The following is a list of those who gain commissions:—

ARMY MEDICAL SERVICE.

Notices to Correspondents, Short Letters, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attenion to this rule.

Dr. Illingworth (Clayton-le-Moors).—Continuation of paper on "Preventive Medicine and Abortive Treatment" received.

Sir Edward Sieveking.—Your Clinical Lecture shall appear in our next issue.

Dr. J. Mortimer Granville.—Paper on "The Management of Gout and the Gouty" received with thanks. It shall appear in an early number.

Dr. A. Ernest Sansom.—Clinical Lecture on "The Dyspepsia of Infancy" received with thanks. Marked for early insertion.

Surgeon-General Messer.—It is unusual to furnish the name of an anonymous correspondent, but we have forwarded your letter to "M.D.," who probably will communicate with you.

Sir Joseph Fayrer, Sir Wm. MacCormac, Dr. B. W. Richardson, Dr. Buzzard, Dr. Braxton Hicks, Dr. Graily Hewitt, Dr. Murrell, Dr. W. H. Day, Dr. Fancourt Barnes, Dr. Godwin Timms, Mr. Anderson Critchett, Mr H. A Reeves, Mr. Henry Morris, Mr. Reginald Harrison (Liverpool), will please receive our best thanks for their communications.

Mr. Carter (Glasgow).—Paper received; proofs shall be sent you in due course.

L. M. D.—Our opinion of the author's views is expressed in a review of the work in our last issue.

Mr. Wilson.—Not at all surprising; the "peculiarity," as you term it, has been known for some time past by those behind the scenes.

Dr. Harris.—The subject is not unlikely to come up again shortly in a somewhat disguised form, when the information kindly supplied will be utilised.

L.R.C.P. (Edinburgh).—The registration is so faulty in the two cities referred to that only an approximate estimate can be formed. The population of Rome is about 350,000, that of Madrid about half a million. In both cases the average death-rate is more than fifty per cent. higher than London.

Physiologist.—The ancients had a very vague idea of the age of animals. Hesiod gravely tells us that the elephant lives a thousand years, the crow ten times as long as a man, the stag four times as long as the crow, the raven three times as long as the stag, and the phœnix nine times as long as the raven. As to this creature, the stories told of him, or her, even by some of the so-called Apostolic Fathers, are so ridiculously incredible as to unfit them for reproduction here.

OBSEQUIES OF A GIANT.

Last week at Tipton, Staffordshire, much local excitement ensued at the funeral of Samuel Murfitt, who was recently exhibited as the largest man in the world. The deceased was 55 years of age. His dimensions were as follows:—Height, 6ft. 1in.; weight, 40 stone; girth of waist, 100in.; and he measured 20in. round the calf of the leg. A hearse could not be found large enough for the deceased's removal, and the body had to be conveyed on a flat. The sashes had to be removed from the windows, and nearly 20 men were employed to get the coffin through the window on to the flat.

A Young Naval Surgeon.—We would advise you, before applying for the post, to read Dr. Curran's article, "The Inner Life and Economy of a Troopship," that appeared in the December number of the *Illustrated Naval and Military Gazette*. It contains all the particulars as to diet, duty, &c., &c., you require.

Dr. Bayfield.—Sorry we are unable to find space for your communication. The scheme is impractical and Utopian, and withal is hampered with such minute details as to be unsuitable for our columns.

ARTIFICIAL FECUNDATION.

H. M. D.—We quite agree with you that a woman who would go through the operation of artificial fecundation, as we have heard it described, would do anything, and would not suffer much loss by going a step further. The gentlemen who have taken up this branch have generally been men of irreproachable *physique*, and it is possible, as you suggest, that this was not altogether foreign to their success in the treatment of sterile women. We thank you for the information as to authors.

Ignotus.—'Twas Coke, we believe, who said that "law was a jealous mistress that brooked no rival," and as to specialism in law and medicine, it was said by the great jurist, Austin, that "if you wish to know any one thing or theory well, you must be content to be ignorant of many other things or theories." As to the particular specialty you name, 'twas practised, according to Herodotus, centuries ago in Egypt.

Bookworm.—You must be misinformed on the point, we fancy, for it is, or rather was, well understood that the late Dr. (afterwards Sir) Thomas Watson enjoyed a royalty of £200 a year or more, for many years before his death, out of his book, and we have heard it stated that, in addition to this, his publishers (the Messrs. Longmans) once sent him, without any solicitation on his part, a cheque for £1,200. The work is now so much out of date as to be almost valueless as a text-book. You are, of course, aware that Lord Macaulay once received a cheque for £20,000 from this same firm.

A Union Doctor.—Yes; the first English Poor Law (27 Henry VIII) prohibited alms-giving under heavy penalties, and as for "sturdy beggars," a member of this fraternity is to be whipped the first time, and if he again offend he shall suffer death as a felon and an enemy of the Commonwealth. The 14th of Elizabeth provided that these terrible, sturdy beggars "should for the first offence be grievously whipped, and burned through the gristle of the right ear with a hot iron of the compass of an inch about; for the second be deemed as felons; and for the third suffer death without benefit of clergy." So cold or cruel is official charity everywhere.

Curiosity.—Yes; Sir W. Thomson holds that the period of the sun's duration of incandescence could not have existed longer than twenty millions of years, and could not endure for as much as ten millions longer. A million or two, more or less, might be thrown in in exact science.

◆

Meetings of the Societies.

WEDNESDAY, FEBRUARY 9TH.

Epidemiological Society of London.—At 8 p.m., Mr. John Moir: Statistics of Small-pox Cases in the West Ham Hospitals during the Epidemic of 1884 and 1885. Dr. John Macpherson: A Memorandum on Notices of Cholera in India before 1817.

Royal Microscopical Society.—At 8 p.m., Presidential Address by the Rev. Dr. Dallinger, F.R.S, on Recent Optical Improvements in the Microscope, and the operation of the Darwinian Law amongst the Minutest Organisms.

British Gynæcological Society.—At 8.30 p.m, Specimens will be shown by Mr. Bland Sutton, Dr. Fancourt Barnes, and others. Dr. Charles E. Fitzgerald: The Use and Abuse of Pessaries.

THURSDAY, FEBRUARY 10TH.

Royal Institution of Great Britain.—At 3 p.m., Prof. A. W. Rücker: Molecular Forces.

FRIDAY, FEBRUARY 11TH.

Clinical Society of London.—At 8.30 p.m., Nephro-lithotomy—discussion on papers read at the last meeting by Mr. Henry Morris, Mr. Marsh, and Mr. Bennett. Dr. Hughlings Jackson: A Case of Crural Monoplegia from Subcortical Disease. Dr. Carrington: A Case of Rheumatic Hyperpyrexia. Living Specimens:—Dr. A. H. Robinson: A Case of Charcot's Joint Disease.

Vacancies.

Doncaster General Infirmary and Dispensary.—House Surgeon. Salary, £100 per annum, with board and residence in the house. Applications, with testimonials, to be sent to the Hon. Secretary not later than Feb. 21st.

Tunbridge Wells General Hospital.—Resident House-Surgeon. Salary, £100 per annum, with board, furnished apartments in the Hospital, gas, firing and attendance. Applications, with proof of qualifications, must be sent to the Secretary on or before Wednesday, 16th February.

Royal Albert Hospital, Devonport.—Honorary Surgical Staff. Applications, with testimonials, should be sent addressed to Chairman of the Selective Committee not later than Friday, the 18th of February.

Appointments

Barron, H., M.B., C.M., M.R.C.S., L.R.C.P., Medical Officer to Christ's College, Finchley, N.

Bickerton, T. H., L.R.C.P.Ed., M.R.C.S., Oculist to the Liverpool Royal Infirmary.

Boys, A. H., L.R.C.P.Ed., M.R.C.S., Medical Officer for the Second District of the St. Alban's Union.

Hutchinson, A. C., M.B., C.M.Aber., Honorary Medical Officer to the Brighton, Hove, and Preston Dispensary.

Pollard, C., M.R.C.S., L.R.C.P., Assistant Medical Officer to the St George's Union Infirmary, Fulham.

Stephenson, W., M.R.C.S., L.S.A., Honorary Surgeon to the Beverley Cottage Hospital.

Vogan, J. N., L.R.C.P.Lond., F.R.C.S.E., Medical Officer for the St. Matthew's District of the Ipswich Union.

Births.

Crossfield.—Feb. 1, at Broadstone House, Dartmouth, the wife of A. K. Crossfield, L.R.C.P., of a son.

Marriages.

Caudle—Barton — Feb. 3, at St. John's Church, Calcutta, Charles E. Caudle, M.D., to Agnes, second daughter of the late Rev. E. G. Barton, late Rector of Etchingham, and of Urmston, Eastbourne.

Deaths.

Alexander.—Jan. 27, at Trinity Square, London, S.E., on his 67th birthday, Charles Linton Alexander, F.R.C.S., L.S.A.

Brunker—Feb. 2, at 38 Belgrave Square, Rathmines, in his 84th year, E. G. Brunker, M.D., F.R.C.S.I.

Daubeny.—Jan. 26, at San Remo, Italy, Henry Daubeny, M.D., in the 67th year of his age.

Massey.—Jan. 29, at Greek Street, Stockport, Thomas Massey, M.R.C.S., aged 66.

Myrtle.—Feb, 2nd, at 243 Oxford Road, Manchester, Andrew Scott Myrtle, M.D., son of Dr. Myrtle of Harrogate, aged 24.

Prosser.— Jan. 30, at Bromsgrove, Worcestershire, Roger Prosser, L.R.C.P.Ed., M.R.C.S., aged 51.

Rawes.—Jan. 29, at Bath, William Wilson Rawes, Deputy Inspector-General of Hospitals, Madras Army, in his 71st year.

Startin.—Jan. 26, at Surbiton Hill, the wife of James Startin, of 17 Sackville Street, Piccadilly, aged 37.

The Medical Press and Circular.

VOL. XCIV.] WEDNESDAY, FEBRUARY 16, 1887. [No. 7.

Original Communications.

WHAT SHALL WE DO IN OUR HOLIDAYS?

A FINAL CLINICAL LECTURE DELIVERED AT ST. MARY'S HOSPITAL, JANUARY 14TH, 1887.

By Sir EDWARD H. SIEVEKING, M.D., F.R.C.P.,
Physician Extraordinary to Her Majesty the Queen; Physician in Ordinary to H.R.H. the Prince of Wales, Senior Physician to St. Mary's Hospital.

> "Dum licet, et vernos etiamnunc editis annos,
> Ludite; eunt anni more fluentis aquæ."
> OVID., *Art. Am.* III, 61

As my term of office, after thirty-six years of interesting and loving labour at St. Mary's Hospital, is about to terminate, and I shall shortly enter upon what, as regards hospital work, may be regarded as a holiday, it has appeared to me not inappropriate, that "the last few words" which I am about to address to you, may suitably be devoted to the consideration of *your* holidays. I may premise that while I regard holidays as periods of recreation, I by no means think that they ought to be periods of sloth and idleness. I therefore propose in the last lecture which I shall deliver from this place, to reply to the question: What shall we do with our holidays?

The bow that is kept permanently strung is known eventually to lose its elasticity and to become more or less unserviceable. The human powers] exerted persistently and exclusively in one direction become overstrained, and to maintain them at their proper elevation, rest and relaxation are absolutely necessary. Apart from the religious aspect of the question, the inculcation of one day's rest in seven, from ordinary labour, embodies a great physiological law, which all nations would do well to recognise; and if this ordinance was necessary in the early history of mankind, the requirements of modern life, with all its excitement, worry and competition, render it still more so. English boys have no reason to complain that the law of rest from work is not obeyed, in the course of their school training. I believe that none of the civilised nations of Europe which lay great stress upon education, allow so many half and whole holidays, amounting in all to a good deal more than a quarter of the year, as the English schoolmaster.

This is a purely educational question, which masters and parents must settle for themselves. In however many points it may present a medical aspect, it does not form the subject of our consideration to-day. We certainly need do nothing to urge the necessity of relaxation in ordinary school discipline.

The matter assumes a different aspect when we take account of the hygiene of the adult English-man, "person" I should say, to be in conformity with modern phraseology; at all events the remarks I wish to make, though having no kind of political bearing, and therefore not involving the rights of women as conflicting with the rights of the other sex, apply to all who have passed the barriers of childhood.

Whatever the Encyclopædists and Rousseaus, of the past century, may have meant by advocating a return to nature, I do not think that they recognised the fact that the chief law of nature regarding man, is the law of growth and development. He cannot stand still. He must either go onward or backward. He must work and strive for advancement; or deterioration, morally, physically, and intellectually, will ensue. Sloth is worse than overwork. For overwork, though it may damage the individual, can scarcely be carried on without benefiting his neighbour in some manner; while sloth is deleterious to the person who indulges in it, and pernicious by the influence it exerts upon everything and everybody in contact with him. But is there no mean between sloth and overwork? The very study of man's constitution appears to afford a satisfactory reply, for we find him made up of so many different elements, that he may cultivate and develop one faculty, while he gives repose to others; by so doing he may render one part more fitted for the service of the other, and insure a more perfect development and growth of the whole.

I start, therefore, with the proposition that the average man, I mean the man engaged in the ordinary occupation of his life, and not suffering from actual disease, takes his rest or holiday, by varying his mode of life and occupation. The holiday should not mean lotos eating. However we may be tossed about on the sea of life we should not imitate the companions of Ulysses and, shirking our responsibilities, sit down by the rippling brook and sing—

> How sweet it were, hearing the downward stream,
> With half shut eyes ever to seem
> Falling asleep in a half dream
> To dream and dream, like yonder amber light,
> Which will not leave the myrrh bush on the height;
> To hear each other's whispered speech;
> Eating the lotos, day by day,
> To watch the crisping ripples on the beach
> And tender curving lines of creamy spray;
> To lend our hearts and spirits wholly,
> To the influence of mild minded melancholy;

and so on.

When I look back over my professional life now of more than forty years' duration, dating from the year I took my degree, I have many melancholy reminiscences of personal friends cut off when they reached the happy stage of professional success, but long before they had attained any thing like the limit of age assigned to man by the Psalmist. In most cases their early death was fairly attributable either to their allowing themselves no holiday or only insufficient ones, or to their employing their vacation time in a way which they probably would not have recommended to their own patients. We cannot all follow the example of Sir Henry Holland, who from an early period of his career as a physician, was able to permit himself annually three months of leave, and whose long life was undoubtedly, as he himself has said, due to the invigorating effect that this salutary influence exerted upon his mind and body, so that within a few days of his death, which occurred if I mistake not when he was 85, he was attending the trial in Versailles of Marshal Bazaine, after the last Franco-German war. We cannot all follow his example literally, in fact, scarcely any professional man can now-a-days, because owing to a peculiar concurrence of favourable circumstances, he was able to say that he would limit his professional income (and he began life with no other) to £5,000 a year. It would probably ruin the professional prospects of the busiest medical man, if he were now to absent himself from practice for three months every year. Nor, however delightful it might be to some, do I think such an amount of vacation necessary, for attaining the main objects which we have in view, that of increasing our fitness and capacity for our regular work. But in whatever line of practice we may be engaged (and I need scarcely say that my remarks are specially calculated to appeal to medical men) a holiday of three to four weeks, ought to be obtained once a year. It cannot be done without making some pecuniary sacrifices, but the advantage gained far outweighs them, and as most medical men's lives are of peculiar importance to a wife and children, they should regard such sacrifice very much in the light of an insurance premium, for which if there be the *res angusta domi*, prudent men willingly forego luxuries, which they are able to dispense with.

The extent of the holiday and the time of the year at which it should be taken, must necessarily depend upon a variety of circumstances, which will guide the individual, and which it would be a waste of time on our part to consider. The point to which I think that we may profitably turn our attention, and which from personal experience, I know to be of real importance with regard to your future medical career, is the question with which I have headed this address: What shall we do with our holiday?

In these days of railways and steamboats, everybody travels, so that "the home-keeping youth of homely mind," of whom Shakespeare speaks, is scarcely to be found. To the many subjects that have a practical interest to the medical student, climatology and balneology, which were scarcely recognised in my early days, have been added. The trading apothecary, now we will hope a thing of the past, used to send his quantum of mixtures, pills, and plaisters, with little reference to diagnosis or therapeutics, and literally pooh-poohed all who advocated preventive medicine or any means of cure not capable of being sent out in a labelled bottle or box. Times have changed, and it has come about that the opposite extreme now threatens us, and there is great danger of an entire and prevailing scepticism as to the value of drugs. I am not one of those, for the longer I live, the more have I learnt to believe in the value of therapeutics properly applied. But at the same time I have never ceased to believe that there are many agents that influence and modify morbid processes, besides those which we are able to measure in a beaker or weigh in our scales. Now, some of these we specially learn to value by personal travel, and the more we travel in our young days, with our eyes open, the better shall we be able to advise and direct those who afterwards entrust themselves to our care. I say advisedly, with our eyes open, for you may meet many who in wandering over the world use only the eyes of their guide-book, and observe nothing for themselves. I say nothing against the proper use of guide-books, but when I see ladies and gentlemen in the sublimest scenery devoting themselves exclusively to the task of turning over the leaves of their Murray or Badeker, or hear them descanting solely on the merits or demerits of their hotels, I cannot help thinking that the *impressions de voyage* left on their minds when they return to the domestic hearth, will be of a very limited and evanescent character. Your minds are now specially receptive, and whatever you photograph on the tablets of your brain will certainly return to your conscious use at some future time. I am a great advocate for making memoranda of the daily events in travel, or they soon become blurred, and the excessive rapidity of locomotion of the present day is an undoubted bar to firm impressions, unless we take some means to fix them for reference.

Some, and I am among them, give a preference to pictorial journals, in the shape of sketch-books. By sketching what you see before you, however imperfectly, you make an indelible impression upon your mind, and the addition of the exact date, with possibly a few explanatory words, will recall to your memory, years after, more precisely what happened at the time, than any amount of mere descriptive prose. If you take a rough outline of the places you visit, you acquire a habit of looking at Nature and the works of man with a careful eye; and you learn to appreciate the glorious effects of colour and form, the peculiar geological or botanical features of the landscape, the habits and characters of the people, in a manner, and to an extent, which no books, no photographs, can serve as a substitute for. I do not assume that you are all artists, but I do assume that any of you can with a little practice make an outline of what he sees before him, and I maintain that the merest outline serves as a valuable record for the future. No one should travel without a small sketch-book and pencil; and if time and previous training allow of a box of moist colours in addition, so much the better.

But where, and how, shall we go? The world is large, and the means of travel many. The second part of the question will probably be best settled when we have agreed upon the former part. I would only say this much now, that the railway of the present can scarcely be regarded in any other light than that of mere locomotion, whereas the old-fashioned stage coach or diligence was itself a school for the traveller by bringing him into constant contact with persons and places, and enabling him to see localities and characters, which he must now-a-days leave the railway to appreciate and study.

If the choice is open to us, I say let us first examine the features of our own country. There is infinite beauty to be found North, South, East, and West. There are many climates in as many directions, and the habits of the people are by no means so identical throughout the land that we may not learn much anthropological lore from our intercourse with them. There are certain broad features which characterise regions, but every region presents many local peculiarities in different parts, which no amount of mere reading will enable the ordinary mortal to appreciate. It is said that the great philosopher Kant, who during a long life never slept more than one night from his home in Königsberg, obtained such a marvellous knowledge of distant people and places, that travellers who waited upon him would not believe that he had not seen and visited them. We scarcely wish to possess such a faculty, and would rather rival our old friend of the Odyssey—*πολλῶν ἀνθρώπων ἴδεν ἄστεα καὶ νόον ἔγνω*—who saw the towns of many men and knew their qualities.

Climate depends upon soil, wind, rainfall, latitude, vicinity to or distance from the sea, geological conformation, the presence or absence of heat, and last, though not least, the amount of sunshine. Some of these climatic influences are, to a certain extent, under the control of man. The aridity or moisture of the soil in a great measure depends upon trees, and destruction of forests or neglect of arboriculture has repeatedly become a serious topic for the consideration of governments. Many Swiss Communes depend for their very existence upon the protective power against landslips and avalanches, upon sheltering pine woods, which are, therefore, under the careful supervision of their ruling powers. Though other hygienic influences have often to be considered in common with climate, in the advice we give to our patients, you must be careful not to confound the two. You may select the healthiest locality in the world for a residence, but if your house is built over a sewer and you inhale sewer-gases, or drink water impregnated with excrementitious matters, you cannot escape their baneful effects. It is not the object of this lecture to touch upon domestic sanitation. I content myself, therefore, with this brief hint that besides climate, in the strict sense of the word, in your visits to new localities you should not overlook what man has done, or is doing, to make them more or less healthy.

Take the east and west coasts of Great Britain in their general aspects, you find that the former is generally drier and colder, the latter the moister and warmer of the two. In ordinary parlance the east is the more bracing, the west the more relaxing aspect. The winds that come from the Atlantic are charged with its emanations, and on contact with the land unload their burden, and the rainfall in consequence which in London averages about 25 inches a year, rises on the west side of England in some places, as at Grasmere in Westmoreland, to above 120 in., and when I was in Skye, I was told that in the vale of Sligachan, under the shadow of the Cuchullin mountains, as much as 174 inches of rain fell in the year. A ridge of hills or mountains materially increases the precipitation of the watery vapour from the clouds; hence, when in travelling from east to west, you cross a hilly district, you will be certain to find a considerable difference in the rainfall on the two sides. This is not the place to estimate the effect of dry or moist climate upon individuals; it varies immensely. I merely wish to attract the attention to a few points that deserve your consideration; the application I must, at all events for the present, leave to you. In judging of the results of the rainfall, you must take into consideration the soil and geological features of a locality. Does the rain run off easily? Does it accumulate and cause pools and marshes? Is it rapidly absorbed by a sandy, gravelly, or chalky soil? or does a clayey bottom prevail which is impermeable to water? These are a few of the points which modify the effects of the rain upon the human constitution. If you are botanists, the character of the flora of a locality, besides having an interest to the special student of this department of Nature's works, may assist you in determining the climatic conditions which prevail.

The influence of winds is not to be considered only in regard to the amount of moisture they carry, but also in regard to temperature, and in regard to the manner in which they affect the temperature of the human body. If you read any of the works of Arctic travellers, you will find that they not only bear, but enjoy, a temperature very much below that which we denizens of the British Isles ever experience; but this is only the case when the air, which is a bad heat conductor, is still; as soon as the air is in movement, every fresh layer of air that is in contact with the body removes a portion of its heat, and therefore when that air is of a low temperature (and especially if more or less saturated with moisture) the caloric is soon exhausted. Of late years we have learnt to look to certain well-protected regions at a high elevation as valuable agents in the treatment of disease. The celebrity of Davos, Wiesen, or Maloja, in the Engadine, where a former St. Mary's man is happy to attend patients you may recommend to him, depend upon the stimulating purity of their atmosphere, lying at an elevation of over 5,000 feet, and being surrounded to the north, east, and west by higher mountains, ranging to nearly 9,000 feet above the sea level. They are thus sheltered from the north and east winds, and enjoying an almost cloudless sky, patients who could scarcely put a foot out of doors in winter at home are enabled to bask in the sun when the thermometer is many degrees below freezing, the only precaution necessary, as Dr. Wise tells us, being the use of a pair of dark spectacles to neutralise the "glare of the snow." The peculiarities of Davos are not commonly found in mountain regions where cold and wind ordinarily prevail, which, therefore, often renders them unsuited for the class of invalids who derive most benefit from that and similar Swiss winter resorts.

When, instead of travelling from East to West, we go from North to South, or *vice versa*, the question that especially suggests itself is the one of temperature. No one should travel, whatever the season of the year, nor in whatever direction he may bend his steps, without being amply provided with extra wraps, because not only is the weather variable, but the temperature varies at different localities and at different times of the day. This last point has to be borne in mind in the selection of climates that are reputed to be warmer and milder than our own, because in many health resorts of the South the contrast between the air before and after sunset is frequently so marked as to become actually deleterious. I shall never forget my surprise when, after leaving London sweltering in an August sun, I reached the Northern Highlands, before the middle of the month, and found large fires in all the rooms. The best protection against the vicissitudes of temperature lies in woollen garments and in wool worn next to the skin. Being one of the worst heat conductors that are employed for clothing, it is suitable for heat and cold, allowing of healthy evaporation from the surface, preventing chills from the condensation of perspiration which renders linen so particularly objectionable as a body covering, and maintaining an even cutaneous circulation, one of the great secrets of health. When you are in health very few precautions may be necessary; still, the question of clothing should never be neglected by the healthiest travellers, for among the many causes of serious disease in both sexes, the effect of damp and cold takes a very high and important rank.

In inquiring, especially for our patients, into the temperature of a locality, we have not only to consider its possible extremes, but the daily range and the mean temperatures of the year and of different seasons. As an illustration, I may quote (*a*) London and Penzance. The metropolis, with a mean annual temperature of 50·39° F., has a mean extreme annual range of 64° F. Penzance, with a mean annual temperature of 51·80°, has only a mean annual range of 49° F.; in other words, Penzance exhibits a much more uniformly mild climate than London. Let me take one example from foreign places much resorted to by Englishmen, Naples, to make the matter more clear. We there find a much higher mean annual temperature than in London, viz., 61·40° F., and still the range is the same, viz., 64° F., showing that to obtain such a result the contrast of summer and winter temperatures must be much greater than it is here. It is to be remembered that in many of the so-called warm localities of the Continent the means of protection against low temperatures are often extremely inadequate, and this and the absence of many sanitary arrangements that we are accustomed to, should always be well considered before we sanction the expatriation of our invalids from home and all its comforts. I have often had occasion to protest against the exaggerated tendency of the present day to seek a cure by mere change of residence, without a due knowledge of the new place recommended, and without any assurance that the patient would find abroad the primary advantages of a well-supplied larder, the decencies and necessities of an English home, as well as the air and water which is to be a sovereign cure for his malady.

It is but right and proper that the Briton should have a preference for the sea, and his taste is not without good foundation, for the air coming over the main is of the purest and most bracing character, and while the healthy are made healthier and stronger by it, there are few disorders which are not cured, relieved, or in some way benefited by the various tonic influences that offer themselves in a sea-side residence. The tonic advantages obtained from the use of the sea bath can scarcely be over-rated, and I advise you to avail yourselves of it whenever time and place permit, and, in parenthesis, I would remark that when you are not at the seaside, the substitute of a sponging bath prepared with bay salt or sea salt, is by no means to be despised. I attribute my

---

(*a*) Sir James Clark on Climate, 1846, Table V.

own health and my entire immunity from catarrhal and rheumatic injuries, to the daily employment of a bath strongly impregnated with salt. Of course at the seaside you expect a special prevalence of winds. In your examination of seaside localities, you will therefore particularly note their aspect, whether the country is flat and the situation more or less exposed or sheltered. You may visit two places, not many miles apart, and find, owing to local peculiarities, which books may mention, but which mere reading will scarcely impress upon your mind, that they differ much in their effect upon the system. In one the digestion may suffer from what is called its relaxing character, in another the irritating prevalence of bleak winds may render it obnoxious to people with sensitive mucous membranes. The same locality often presents different features in places not far apart, owing to difference of elevation and difference in the soil, vegetation, or surrounding objects. Even the position of the rooms of a house are not beneath your observation when you have to deal with delicate individuals. The Italians have a proverb: *dove non viene il sole, viene il medico*—the side the sunshines not on, brings the physician, and in our sunless climate, the gist of this saying should never be lost sight of, and we should try to secure as much sunshine as possible for ourselves. You who reside in and about St. Mary's Hospital, may consider yourselves fortunate in occupying a site from eighty to ninety feet higher than the fashionable denizen of Belgravia, with an undoubtedly more bracing climate than that of the damper and lower-lying regions of Brompton. If you pay a visit to one suburban seaside locality, now dignified by the sobriquet of London-super-Mare, you will find a considerable difference in the Kemptown end of Brighton, which is situated on a high cliff, from that of the west end, which is flush with the sea, but more protected towards the north and east. I need scarcely remark that you must at the seaside consider all those climatic influences that I have adverted to quite as much as you would inland, but you have in addition those special characters of air, temperature, and sunshine, which depend upon the proximity of the ocean.

But probably you will not be satisfied with remaining at the seaside, but will long to try the effects of a voyage. There are few who seek an intimacy with Neptune, who do not pay for their temerity. He generally exacts tribute in a most unpleasant manner, and yet his work soon subsides, and he rewards you for your determination and pluck. There is a great difference in the susceptibility of individuals to that most unpleasant infliction, sea-sickness. I have known a captain in Her Majesty's service, who never went to sea without at first experiencing it, while I have been acquainted with landsmen (and women) who have not known, in long voyages, what it was to be sick. Much doubtless depends upon the nervous system, much upon the state of the chylopoietic viscera, and I think it a good rule to make sure before going on board a vessel, that the liver is performing its functions well, and that the bowels have been freely relieved. Of the nostrums recommended for sea-sickness there is no end; much of it depends upon the ventilation of the cabins, and the constant change of our own centre of gravity and that of surrounding objects. Most people get their sea-legs and stomachs after a short time; some find soporifics, others alcoholic stimulants, and particularly champagne, of use. The sovereign remedy, however, generally is habit, and when your brain and heart have got accustomed to the new demands made upon them, a life at sea becomes enjoyable. The air on deck is of the best, and if the voyage be not too long, the new aspect under which life is presented to you, affords much to amuse and interest.

As regards health and rest of mind, I consider few things to be more beneficial than a voyage. You seem to get more good in a short space of time, more thorough renewal of life, from this process than from any other. A friend of mine, a well-known American physician, told me that as all the members of his family were good sailors, they considered their annual migration to Europe the greatest possible advantage, not so much on account of their visit to England and France, as on account of the benefit they derived from the hygienic influence on body and mind of the three weeks spent at sea. If you have the opportunity of taking a cruise in a well found yacht, do not let it slip, sea-sickness is much less formidable in a sailing-vessel, but even if you are compelled to avail yourself of steam, let not the disadvantages of this mode of locomotion deter you from becoming familiar with the sea; there are advantages in it, upon which I need not dwell, which may carry great weight with you.

We might now, fitly perhaps, cross the sea and ponder for a short time upon what the Continent of Europe offers to the student during his holidays. But I wish before doing so, to review one or two other points of interest to the gentlemen of education in England. No country possesses so large a number of objects of historical interest, from the time of the Druids, through the Roman to Saxon and to Norman periods, down to the reign of our gracious sovereign Victoria. The better your knowledge of the history of your country, the more will you be able to appreciate these various objects, and let me tell you that although the architecture of the present day may be carped at, the cathedrals of England and many ancient structures devoted to other purposes, may vie with, if they do not surpass, anything to be found in other countries. But to the medical man the health resorts offer objects of particular professional interest, which need in no way interfere with his artistic, archæological, or historical pursuits. It is always well to have one's main object in view, round which other minor objects readily group and attach themselves.

Our mineral waters are not of much account generally, compared to the more potent springs which other countries offer. Still they are by no means to be despised, and at all events the town of Bladud has been celebrated from the days of the Romans and its waters continue to be used with great benefit by crowds who resort to Bath. Extensive remains of the baths built by the Romans are still to be traced, and it is evident that here and elsewhere, they availed themselves of the sweating process, as sudatories are universal in old Roman baths. The temperature of the Bath waters, which rush out in a great body from the bowels of the earth, is at first 116° F. and is therefore too high to be employed before it is lowered. They are of considerable efficacy in chronic rheumatic and gouty affections, in certain forms of skin disease, some dyspeptic conditions and some forms of paralysis as lead palsy. The mineral ingredients contained in the Bath waters are not very copious and exercise less influence than is exerted by the prolonged immersion in the bubbling warm water. We have other mineral springs, but none so warm as Bath. The temperature of Buxton water is only 92° F., therefore can be used internally and externally without being cooled. It has a special reputation in gouty affections. Matlock again which is a favourite place of resort, south-east of Buxton, has a perennial warm or tepid spring of 82° F. The disadvantage of Buxton is, that at a high altitude of 1,000 ft. above the level of the sea, it is both cold and wet; undoubtedly bracing for those who carry with them a certain amount of vigour, but likely to prove trying to persons of a weakly constitution. Then, if we travel north from Derbyshire we come to a watering place in Yorkshire, which has long enjoyed a considerable reputation in the treatment of cutaneous disorders on account of its sulphurous springs. It has a cold, bracing climate, but Harrogate of which I am now speaking, offers to invalids the advantage of a pure chalybeate, also, so that various forms of anæmia and its consequences, are frequently treated at that place, with marked benefit.

Our friends on the other side of the Tweed, however many attractions they may offer in point of scenery and poetical associations, and however many their mountain and sea climates that give health and strength to the weary townsman, have even less to boast of than their English compatriots, in respect of mineral waters. Moffat and Strathpeffer, both containing chlorides and sulphates of soda and sulphuretted hydrogen, are employed in similar cases, as the sulphurous springs of Harrogate, but are better known to tourists on account of their romantic scenery, than to invalids for their curative virtues.

When you wend your way southward you come upon the powerful bromide springs, probably derived from a subterranean reservoir of concentrated sea water, at Woodhall in Lincolnshire, south west of which the Spa of Leamington deserves your attention, a place that has had a reputation through its saline and chalybeate springs since the middle of the 16th century. The neighbourhood of Leamington is intensely attractive on account of its vicinity to Coventry, to Stratford on Avon, to Warwick with its grand mediæval castle, to Guy's Cliff and to Kenilworth castle of Elizabethan fame. A holiday may well be devoted to running about and studying the highways and bye-ways of Warwickshire. When we come south of the Thames we find two places of ancient renown due to their mineral waters. One, Epsom, may well exclaim, my glory is departed; it is in a therapeutic sense, *vox et præterea nihil*, for the famous Epsom salts are now made from magnesian limestone and I am ashamed to say, that although I have often been at Epsom, I have never yet seen the spring which in the last century was a resort of the fashionable world. Epsom salts were at the end of the 17th century first condensed from the water of the saline spring, by Dr. Grew, but have for more than 60 years been produced on a large scale from dolomite or magnesian limestone. Tunbridge Wells on the other hand, distinguished for its chalybeate, still enjoys a medical reputation, though I fear that it cannot bear comparison in its efficacy to the more powerful analogous springs that railways and steamboats rapidly convey our patients to on the Continent.

Whether we spend our holidays in Great Britain or on the Continent, the medical man should not forget to visit the hospitals, wherever they are are. He can scarcely fail to learn something regarding the treatment of the sick or the administration of the institution, even by a cursory survey. Manifest faults will warn him to avoid them at home; manifest improvements upon the system he has learnt, will bear fruit when he acquires a position to introduce them elsewhere. But wherever you go, be careful not to form hasty judgments. Be mindful of the possibility of your own shortsightedness; and remember that there often may be a justification or a local cause for things that at first sight appear objectionable, and which a more perfect knowledge may show in a different light.

If I have taken you at railroad pace over the ground hitherto, I fear I must use even more expedition in touching upon the question of continental travel during your holidays.

You may remember that Horace tells us:

Cœlum non animum
mutant, qui trans mare currunt.

I entirely differ from this opinion, and hold strongly that nothing is more refreshing to the mind as well as to the body, than to cross the sea and to learn the habits and modes of thought and action, of adjoining and, if possible, distant nations. I do not agree with Dr. Johnson's epigrammatic definition of patriotism, as the last refuge of a scoundrel; on the contrary, I regard an enlightened patriotism as much a virtue, as I regard domesticity and family life as the groundwork of a strong and virtuous social polity. But patriotism is not to be confounded with narrow egotism, as little as domesticity with niggardly exclusiveness and a contempt of all strangers and foreigners. On the contrary, we shall probably learn not only to love more our own country and own hearth, and, what is of more consequence, be enabled to serve both more effectively, if with greater experience and enlarged views on mankind, we return to the daily duties of our English life. Now, if you agree with me that we cannot, in the first instance, better spend our holidays than by devoting them to making ourselves acquainted with Britain, I daresay you will also agree with me, that we shall derive special pleasure and profit from wending our way afterwards to those nearest lands from which earlier or later most of us have sprung. We see in them and in their people many features which are more or less typical of John Bull, and which, though modified by his insular position and by intermarriage, often suggest to the observer his Anglo-Saxon or Norman origin. I have in Normandy, in the Netherlands, in Lower Germany, and Denmark, to which I particularly allude, often been surprised by unexpected resemblances, quite as much as with the differences that, perhaps at first sight, are most striking. Our language, our literature, our politics, our social customs, have ever been more or less associated with those countries, and our very geological structure, divided though we are now by the Silver Streak, shows how in earlier periods of the earth's history, we were even more closely united. I for one sincerely trust that we may never lose the protecting embrace of the sea, for much as I desire that we should cultivate the amity and intercourse of nations, I should as little desire a railway from England to France as, to compare great things with small, I should yield to the most friendly neighbour's desire to facilitate our intercourse by breaking through the party wall, and thus establishing a more ready communication than that afforded by our house doors. A man must remain master in his own house, and anything that, ever so remotely, imperils the independence of a nation is to be as much avoided as that which might weaken the individual's authority over his own domicile and family.

You will not find any particular advantages in the sea coast residences of the regions alluded to. In that respect I think I may say, without risk of contradiction, that we possess everything that the nearer seaside watering places of the Continent offer. The bathing accommodation is rarely so good as, and the habits of the bathers are different from, curs, and not quite to our tastes; while we must go much further afield to find any material difference in the climate. We must quit the shore and go inland if we desire to meet with objects of special medical interest. Let Walter Scott be your guide and take you first to the Ardennes, where, besides lovely scenery and historical reminiscences, you will find the springs of Spa, which has given its name to serve as a generic title for all mineral waters. One of the most powerful chalybeates familiar to us, it has, especially since the days of Peter the Great, attracted the anæmic and exhausted of all countries, and continues, by its salubrious air, its charming situation, and valuable therapeutic powers, to draw crowds of sick and convalescent people. No less than two resident English medical men find it profitable to practice at Spa.

If you quit Belgium and enter the frontiers of Germany, you find that the dormant volcanic energies of the bowels of the earth, supply you with a large number of the most various and powerful mineral springs; of which Aix-la-Chapelle, the ancient seat of Charlemagne, with its sulphur and carbonic acid baths, is the first to greet you. Thence you will probably extend your tour to the valley of the Rhine and its tributaries, where the alkaline waters of Neuenahr and Ems, the brine springs of Kreuznach, the strong chalybeate of Schwalbach, the chloride of sodium waters of Homburg, the thermal waters of Schlangenbad (which, according to Sir Francis Head, make you absolutely enamoured of yourself from the cosmetic influence they exert), and others, deserve your close attention. You may always be certain to be well received by the local practitioners if you honour them with a call, for they are naturally glad to see a *confrère* who may become a means of sending them patients. Besides, I may state, *en passant*, that it will be a comfort to your patients, not only to be assured that you have a personal knowledge of the locality, but also that you are acquainted with the medical men. In making your memoranda it is of use to note whether they can converse in any language but their own, and particularly, as John Bull is rarely a polyglot, whether English is among their acquisitions. Having regard to your patients, the position and charges of the hotels, the facilities of communication, and the particular features of the locality, are also matters of no small importance in a practical point of view. If time permits, a visit to the more distant baths of Bohemia will well repay you. Here Franzensbad, Töplitz, and, above all, Carlsbad renowned for its beneficial action in diseases of the liver, in gout, in diabetes, will attract your notice. Going south, Gastein, Reichenhall, and Ischl are worthy cf a visit, and you then approach the mountains of the Tyrol and Switzerland, where endless health resorts, with and without mineral springs, attract the weary and the sick. Detailed descriptions of these places are here quite out of the question; I must refer you for them to the many monographs that exist, and which you will find in the medical libraries. But permit me, before closing, to cast a bird's eye view over France, and as we last assumed the tourist to be in Switzerland, we cannot do better than go to Savoy first, now a French department, and examine the waters of Aix-les-Bains, which you must be careful not to confound with the German town already mentioned called Aix-la-Chapelle or Aachen. Both date their name and celebrity from Roman times, Aix being merely a corruption of Aquæ. Both owe their medicinal celebrity to water of the same character and influence, for both are sulphurous. A special excursion should be made to the Pyrenees, which exhibit much to interest the medical observer, with its Cauterets, Bagnères de Bigorre and Luchon, after which Pau, Biarritz, and its neighbouring pine forests at Arcachon, and the Auvergne, deserve attention. This neighbourhood should not be quitted without an examination of Vichy, whose waters occupy a similar position to those of Ems, and are both much frequented by the dyspeptic, the gouty, and the sufferers from the many maladies of the mucous membranes, whether affecting the thoracic or abdominal viscera.

The Riviera, of which you have probably heard much, and which occupies the narrow strip between the Maritime Alps and the Mediterranean, is scarcely within the limits of an ordinary holiday excursion, and should be visited at a time from October to April, when few of us can escape the thrall of practice.

My paper, and I fear your patience, are now exhausted. I must leave whatever else I should like to say to my successors. But I cannot conclude without a word of practical advice with regard to your future patients. Do not, as far as you are concerned, allow them to visit foreign watering places without taking special directions from the local medical man, whom you should aid by giving him a proper account of the patient's previous history and malady. We might well imitate some of the Bath doctors, especially in Germany, by attending more rigidly to questions of diet. The Englishman who goes to a foreign watering place and helps himself at his own discretion to the waters is very likely to pay a penalty for the experience required for their proper use. There are generally a variety of springs, which do not by any means possess the same properties, and which require to be employed in different ways and under different circumstances. But one word more and I must conclude. Never attempt to do too much in your holiday. It is better to do a little well, than much imperfectly. How you should go was a part of the question I put at the commencement of the lecture, which I have not time to answer except to this extent: Go, whether on foot, by coach, by steamer, railway, or bicycle, so that you may gather in much fruit to the garner of your memories, that you may say conscientiously, *et hæc olim meminisse juvabit.*

UNUSUAL SITE FOR HYDATID CYST; AN ADDITION TO THE RECOGNISED VARIETIES OF INTRASCROTAL DISEASE.

By PHILIP E. MUSKETT, L.R.C.P. Ed.,
Honorary Surgeon to the Sydney Hospital, Australia; Medical Superintendent, Quarantine Station, Port Jackson.

It has probably fallen to the lot of most surgeons in the practice of their profession, to have met with hydatid cysts in different regions of the body, and yet, so far as my recollection serves me, no case of intrascrotal hydatid has been recorded. This is the apology I have to offer in introducing the subject to your notice, and if I be in error with regard to a prior record, still I trust there will be found sufficient points of interest in the present case to render its narration not altogether uninteresting.

The question as to the likelihood of any tumour or swelling being hydatid should, in Australia at least, always be present in the surgeon's mind; and in the differential diagnosis of such cases, due consideration must be given to the query "Can it be hydatid?" Numerically—I speak from a town point of view—the disease will inevitably increase, for new country is being continually opened up by railway extension, and patients are thereby enabled to have greater facilities for consultation and treatment. Its recognition, therefore, will be rendered easier by the fact that its presence is not altogether unexpected, and the surgeon consequently will be less likely to fall into error, as the maxim "forewarned—forearmed" will apply to matters surgical as to most other things. In my own case, however, I must confess that till the cyst itself escaped from the aperture left by the trocar and canula, and that ten days afterwards, the true nature of the disease was not recognised, as will be detailed subsequently.

As to unique situations for hydatid disease in my own experience, I have found after death, in Douglas' pouch, a cyst the size of an orange, in a young girl who died of cardiac trouble. Had opportunity permitted an examination during life it would doubtless have given rise to some difficulty in diagnosis. I have also been present at an autopsy where a cyst was met with in the pericardial sac. While house surgeon at the Sydney Hospital I saw a cyst the size of a hen's egg, situated over the left deltoid muscle, which was taken to be an ordinary fatty tumour till it was exposed by the scalpel. A few weeks ago a young infant at the breast, sent in by Dr. M. H. Long, of Redfern, and operated upon by Dr. Harman Tarrant, at the same hospital, was found to have several distinct hydatid cysts, enclosing daughter and granddaughter cysts, in the left axillary region, dipping and burrowing deeply down behind the scapula.

The diagnosis of intrascrotal tumours has always been beset with difficulty, and although no mention is made by the accepted English authorities, as to the possibility of scrotal hydatid disease, yet, with us in the Southern world, it must have distinct claims for careful consideration. Bryant, who has written fully on scrotal and testicular disease, makes no mention of hydatid; neither does Erichsen, though the latter records instances of it in the breast, in the neck, and three interesting cases occurring in muscle—one in the deltoid, one at the outer edge of the latissimus dorsi, and one in the biceps.

As the case I have to record is somewhat interesting, I have endeavoured to give a full history. The patient, A. T., æt. 25, a native of Lancashire, was brought out to Brisbane by his parents in 1864, when he was three years of age. In 1874 he was residing at Gympie (Queensland), a gold-mining township, situated in a sheep district, where the water is very bad, being obtained from waterholes sunk in the ground. In 1878 he first noticed a swelling in the right scrotal region, which began at the lower part and enlarged from below upwards. He took no notice of it for some considerable time, and was in the Temora rush in 1880, at which latter place he remained for fourteen months, returning to Gympie in

1882. The swelling at the beginning of 1884 was nearly the size of "two shut fists," and immediately prior to this had enlarged very rapidly. It caused such dragging pain from its weight that he at last sought advice, and consulted the late Dr. Macartney, of Townsville (Queensland), who tapped him and drew off nearly half a pint of "dirty-looking fluid." After this tapping it began to swell again, and soon reached its former size. Eight months afterwards he consulted Dr. Macdonald, of Rockhampton (Queensland), who re-tapped him, withdrawing not so much fluid as on the first occasion, about a quarter pint, which was much clearer than in the former instance. The latter surgeon then injected iodine into the sac, which did not give rise to much constitutional disturbance; but in three or four weeks' time it began to swell, and rapidly attained its old dimensions.

He subsequently found his way to the Sydney Hospital, and was admitted July 16, 1886. There was an intra-scrotal tumour about the size of a large emu egg on the right side. It was smooth in outline, and in its general contour nearly oval. The tumour was tense and dull on percussion, but gave to the fingers on palpation the sensation of fluid within. There was no impulse on coughing, and it was irreducible. The position of the testicle, at its posterior part, was made out by the presence of testicular sensation. The cord could not be clearly defined at the upper portion of the swelling. Light was transmitted by the ordinary manner of procedure, and finally, as was mentioned previously, the history had been that of an eight years' growth, painless except from its mere weight.

The house surgeon (Dr. Westrum), on July 17th, the day after admission, tapped him with a fine exploring trocar and canula, and evacuated about one ounce of "serous-looking fluid," of "pale yellowish tinge." A few days afterwards his temperature rose repeatedly every evening two or three degrees above the normal, being attended with much heat and swelling about the tumour. I now determined (July 30th) to empty its contents, and for this purpose used a full-sized trocar and canula, giving exit to about six ounces of purulent looking fluid. After this a good deal of pus daily drained away, and feeling satisfied that there was something demanding freer outlet, I proposed (August 10th) to open up the scrotum antiseptically on the following morning, insert a full-sized drainage tube, and then stitch the cut edges of the tunica vaginalis and integument together. In the afternoon of the same day, however, an hydatid sac partly forced its way, and was partly extracted, through the opening left from the tapping ten days previously. It presented the usual and unmistakable characters of an hydatid sac, being greyish in colour, translucent and elastic, and in its collapsed condition was of such a size as would about fill an egg cup.

From this time the swelling gradually subsided, the sinus ceased to discharge, the scrotum returned to its normal condition, and the patient was subsequently discharged, cured.

It may not be out of place to mention here, that I have seen the spontaneous expulsion of an hydatid sac on two other occasions, both in cases of abdominal hydatid, which had been tapped some time previously. In the latter of these, in which, I imagine, the expulsion was affected by a process of inversion, I had established adhesions between the parietal and visceral layers of the peritoneum, prior to tapping.

The Mortality of Foreign Cities.—The annual death-rates per 1,000 in the principal foreign cities, according to the last weekly returns communicated to the Registrar-General, are as follow:—Calcutta 34, Madras 34, Paris 25, Brussels 26, Amsterdam 22, Rotterdam 27, The Hague 19, Copenhagen 23, Stockholm 24, Christiania 19, St. Petersburg 34, Berlin 23, Hamburg 31, Dresden 14, Breslau 27, Munich 23, Vienna 27, Prague 33, Buda-Pesth 33, Trieste 41, Rome 29, Venice 29, Cairo 39, Alexandria 38, New York 29, Brooklyn 24, Philadelphia 22, and Baltimore 20.

TREATMENT OF PHTHISIS BY GASEOUS ENEMATA.

By Dr. ALFRED DRYSDALE,

Cannes, Riviera.

Much interest has been displayed by Riviera physicians in a new method of treating phthisical, bronchial, and asthmatic sufferers, introduced by Dr. Bergeon, of Lyons. Dr. Bergeon's mode of procedure is simple, though from considerations of delicacy (perhaps false) somewhat difficult of application in the case of English patients at all events. As much as one litre at a sitting of pure carbonic acid gas, which has previously been passed through half a litre of a mineral water known as *Eaux Bonnes*, which is impregnated with sulphuretted hydrogen, and resembles somewhat our Harrogate water, is slowly injected into the rectum, the process occupying at least twenty minutes. The gas is absorbed by the veins and lacteals, and so thoroughly permeates the system that after a few minutes a pronounced odour of sulphuretted hydrogen is detected in the breath. The time chosen for giving the enema is an hour before or three hours after a meal, and after toleration has been established two or three injections may be administered daily.

Great results are claimed by Dr. Bergeon for his mode of treatment, which he has pursued during the last two years. In early phthisis two or three weeks of this treatment procured arrest of the morbid process, and a few months, a cure. The pulse is lowered, temperature falls, night sweats cease, appetite returns, expectoration rapidly diminishes, loses its purulent character, and the cough becomes less frequent. Even in laryngeal phthisis, when all local or constitutional treatment has failed, rapid amelioration has been obtained.

In reading the above statements—Dr. Bergeon's own—we are involuntarily reminded of the glowing pamphlets of charlatans—the results seem to us to point either to excessive credulity or hopefulness, or to dishonesty on the part of the person narrating them. But in this case, where the treatment is advocated by a Professor of the School of Medicine at Lyons, and where the matter has been brought before the profession in the most orthodox manner by communications to the Paris Academy of Sciences and of Medicine, no suspicions of the kind need be entertained. There is no doubt whatever that the sulphuretted hydrogen thoroughly permeates the lungs, but whether by doing so it produces all the favourable effects claimed for it, can only be decided by trial. At the first sight it does not appear on the face of it why the gas introduced by the bowel should act differently from the gas introduced by the stomach, as it is when the waters of Harrogate, &c., are taken, or when inhaled, though Dr. Brown Séquard has long ago demonstrated the fact that the gas is poisonous only when inhaled. Again, it is well known that bilious persons often secrete large quantities of sulphuretted hydrogen gas, which is voided by the bowel, and yet no relation between this and immunity from lung disease has been observed. Of course the theory which first directed the researches of Dr. Bergeon was that phthisis was directly caused by the presence of bacilli in the lungs; the carbonic acid gas was meant to act as a carrying medium by which sulphuretted hydrogen might be introduced into the lungs with the purpose of poisoning and destroying bacillar germs. The reason why this object could not be gained by the simpler method of inhalation is that sulphuretted hydrogen is one of the gases which destroy life by causing spasm of the glottis. There can be no doubt that the object of Dr. Bergeon, *i.e.*, the permeation of the lung tissues by sulphuretted hydrogen gas is completely achieved by the method employed, but whether the further and ultimate object of curing phthisical patients will be attained can only be proved by experiment and the lapse of time. Many of us bearing in mind the undoubted heredity of consumption, the fact that whole families, the members of which perhaps are scattered over the face of the earth and placed under totally different conditions of occupation and climate, have been known to succumb to this disease, cannot accept the presence of bacilli or their germs as its cause, and only undisputed results will be able to convince us of the efficacy of this treatment.

Dr. Bergeon, however, has no doubt of his power of producing the most brilliant effects, and has certainly shown us that his confidence is unbounded in his own success. Dr. Cazin, well known throughout France for the able manner in which he conducts a large hospital near Boulogne containing 500 scrofulous and tubercular children, has recently paid a visit to Mentone where his wife is under treatment for bronchitis. Dr. Bergeon delivered a lecture there to twenty-two doctors, and explained and illustrated his method. Since then many of his hearers, among them M. Cazin himself, have administered the injections to their patients, and though sufficient time has not yet elapsed to enable a final judgment to be pronounced, the results are said to be satisfactory.

Those of my readers who desire more detailed information will find it in Dr. Morel's pamphlet entitled 'Nouveau Traitement des affections des voies respiratoires d'apres la Méthode, du Dr. Bergeon," (published by G. Masson, Paris, Boulevard Saint Germain).

Clinical Records.

ST. MARY'S HOSPITAL.

Concussion of the Brain with Cerebral Hæmorrhages—Convulsions—Subsequent Pneumonia and Death.

Under the care of Mr. A. Trehern Norton.

From Notes by Mr. P. A. Lloyd, House-Surgeon.

W. S., a cab-driver, æt. 55, was admitted as an in-patient at St. Mary's Hospital on August 1st, 1886, having been thrown from the box of his cab and fallen on his head. On admission he was quite unconscious, the pupils were slightly dilated and equal, and the extremities were cold. The patient was breathing stertorously, and the pulse was slow and rather full; there did not seem to be any paralysis of the limbs. Before he could be got to bed he had two convulsive seizures; the attack began with rigidity in the right arm which afterwards spread to the right leg, and then to the other side of the body. The tonic spasms after a few seconds gave place to general clonic spasms, accompanied by great difficulty in breathing; and after about two minutes the patient became quiet, and presented again the same symptoms as on admission. A third attack occurred about a quarter of an hour after admission, and was just like the preceding ones save that it lasted rather longer. There was a scalp wound two inches long on the left side of the head about midway between the left ear and the occipital protuberance. The wound was dressed with dry dressing, and a bandage applied. He was ordered a five-grain calomel powder, and an ice bag was applied to his head. Next morning he had recovered consciousness, and then said he had been in the hospital about a year before with concussion, from which he quite recovered. To-day he had some difficulty in breathing, and coughed up some bronchial mucus, but not much more than he usually did. The pulse was weak and intermittent, and he was very sleepy. The bowels had been freely open and urine was passed naturally. The urine was acid, sp. g. 1020, contained a trace of albumen, but no blood or sugar.

On the 3rd the patient was slightly cyanosed, had great difficulty in breathing, the respirations being 40, and the pulse 120 to the minute. On examining his chest it was found that he had extensive œdema of both lungs, more especially the left; and also that the heart was acting feebly, so he was ordered a mixture containing ammonia and bark, and brandy was also administered. Slight facial paralysis was noticed for the first time to-day on the right side; there was no other paralysis.

On the 5th, signs of pneumonia set in on the left side the patient became restless and delirious, and at night he was almost comatose; the face and neck were markedly cyanosed. He continued in much the same condition till the evening of the 10th when he died.

The temperature on admission was 97° F., it rose on the 3rd to 103° F., and ranged between 100° F. and 101° F. till the day before death when it again rose to 103° F.

On post-mortem examination the wound on the scalp did not expose the bone; after removing the skull-cap large hæmorrhages were found on the surface of the brain over both occipital and frontal lobes. The brain was healthy except for a punctiform hæmorrhage in the left optic thalamus, and a rather larger one, implicating the right facial nerve near its superficial origin from the medulla. The left lung was pneumonic in the lower lobe, and both lungs were very œdematous. The heart was large and the muscular tissue soft, the kidneys were slightly granular. There was an old fracture on the right side of the occipital bone which was entirely repaired. It did not appear to have implicated the large venous sinuses.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

Friday, February 11th, 1887.

Dr. Broadbent, President, in the Chair.

Discussion on papers read at last meeting by Mr. Henry Morris, Mr. Marsh, and Mr. Bennett on

NEPHRO-LITHOTOMY.

Dr. George Johnson alluded to a case in which all the symptoms pointed to calculus on the left side, but at the operation the left kidney was found to be healthy, and five stones were removed from the right kidney. Looking back on the cases of stone in the kidney which he had met with in his experience, he regretted that he had not possessed our present knowledge of what could be done for relief of stone in the kidney. At present he could confidently tell the patient that, although physic might not do him much good, surgery could do a great deal.

Mr. Knowsley Thornton said he had first cut down on the kidney for stone in 1879 or 1880, and was then much disappointed to find a large tubercle kidney without any stone. This case impressed him with the difficulties in the way of arriving at an accurate diagnosis. In any other case he should have preferred to open the abdomen over the kidney for the purpose of diagnosis, removing the stone, if necessary, by another incision in the groin. He related a case where, after the operation for relief of calculus in one kidney, it was found necessary to cut down on the other and remove other stones. In April and June, 1884, he removed two stones by the lumbar incision, both patients being males. In his fourth case he employed the combined method, and this was the only fatal case. The case, it was true, was an unfavourable one, and he was unwilling to operate. The patient was an elderly Frenchwoman in a bad state of health, and she died from suppression of urine in twenty-four hours. In another case, in consultation with Mr. Morrant Baker, the combined operation was performed and the result was very successful. Coming to the general question of operation, whether it should be by a lumbar incision or by the combined method, he said it should be remembered that with the lumbar incision surgeons of considerable experience had failed to reach the kidney at all, and in others the stones were not discovered. He thought it very rash to stick a needle into the kidney in all directions to find the stone, although no apparent harm followed the operation—at any rate for a time. While the lumbar operation might be a proper one in a limited number of cases, in the majority the patient would have a better chance with the combined method for these reasons: 1. That the kidney will always be found; 2. That a healthy kidney would never be cut into, and the damaged organ left intact; 3. That the peritoneum would never be damaged by incision or otherwise, and if an injury did occur it could be seen and dealt with. In many cases the removal of the stone through a small clean cut in the loin was preferable. As to the ambiguity of the symptoms he pointed out that in disease of one ovary the symptoms were often referred to the other side.

Mr. Bernard Pitts quoted the case of a woman who had a swelling in the left groin and pus in the urine. He cut down on this and found a suppurating kidney. The patient was much relieved after the operation. The second case was a man who had had an injury, following which he had had pain in the left loin. He cut down on the kidney and found a stone, and for three or four weeks the patient went on very satisfactorily. No urine came from the wound. This patient subsequently had rigors and fever and died. At the *post-mortem* two other small stones were found in the kidney with suppuration in the surrounding structures. The third case was about a month since, with bladder symptoms of twelve years' standing. Pus in urine but no pain. On examination there was definite resistance in the right loin. He cut down, and on opening the pelvis a small quantity of offensive pus escaped, and a stone was found and removed. The patient went on well for a time, and then his old symptoms returned, and he was still very bad.

Mr. Morrant Baker alluded to a patient who was shown at the International Medical Congress in 1881, with perinephritic cyst, who subsequently began to suffer from suppuration in the neighbourhood of the kidney. The kidney was removed by a lumbar incision, and the patient did very well and made a good recovery. After a period of perfect health he again fell ill, and had symptoms of hectic.

Mr. Godlee quoted the case of a man from New Zealand with marked symptoms of right renal calculus. Mr. Beck cut down on the kidney and pricked it, but failed to find a stone. Later on he came under Mr. Godlee's care, and he cut down on it again, and examined the kidney very carefully, but failed to find a stone. He left the hospital still complaining of his symptoms, and some days later passed a small stone. Another case was that of a young man with a stone in his ureter, which resulted in the formation of an abscess. A lumbar incision was made, but no stone was found. He subsequently had attacks of renal colic and suppression of urine, of which he died. At the post-mortem the stone was found impacted halfway down the ureter. Had the incision been made in the middle line and the ureter examined, it might have been detected. One objection to this plan was certainly the possibility of a ventral hernia.

Mr. Bruce Clarke said he would like to allude to the difficulty of diagnosis. He had an interesting case a short time since. A man had symptoms of stone in the kidney, but for several reasons it was decided not to interfere. When he died a week later it was found that an aneurism had ruptured into the psoas muscle, dissecting up the lumbar plexus, &c. It was, he said, very fortunate the operation was not performed. As to the choice of incision, he recollected a case where on a second operation having to be performed by a lumbar incision, the very greatest difficulty was experienced in finding the kidney.

Dr. Burney Yeo asked what were the precise indications for surgical interference? At Contrexéville he had been shown a large number of renal calculi which had been expelled *per vias naturales*. The course of treatment implied the drinking of large quantities of the waters—as much as eight quarts a day.

Mr. A. Pearce Gould said he had shown a woman from whom he had removed a stone last year. She was forty years of age, and there was a history of an injury fifteen years previously. She had a renal tumour on admission, and her urine contained a considerable quantity of pus, so it was decided to explore the kidney. That was done on November 27th, and the swelling was found to contain a good deal of pus. On being freely opened and on introducing the finger a stone was felt just within the lower part of the kidney. This was removed and the woman made a good recovery. Since renal surgery had advanced a certain number of kidneys had been explored without any stone being found, and some explanation of this was desirable. It was a matter of common observation that sometimes the symptoms existed without any stone, and sometimes stones were present and gave rise to no symptoms. He thought Mr. Knowsley Thornton rather exaggerated the importance of the laparotomy operation.

Mr. Coupland said that physicians had no alternative but to hand their patients over to the surgeons. He thought one of the greatest justifications for surgical interference was to be found on the *post-mortem* table.

Mr. Tom Smith asked Mr. Knowsley Thornton whether he considered that by opening in the front he had an infallible method of discovering whether stone was present or not in the kidney. In any case there was incontestable evidence that no such diagnosis could be relied upon even from the front. He knew of three cases where he had held the kidneys in his hand, all of them containing stone, and yet neither of them was thought to contain stone until cut open. Further, the kidney which had once formed a stone was likely to form another, and this had a bearing on the value of surgical interference. Personally he yearned to remove stones from kidneys, but there could be no doubt that drinking large quantities of water, mineral or otherwise, did good in some cases, and ought always to be tried before cutting down.

Mr. Knowsley Thornton said he did not consider the abdominal incision infallible. He thought it was easier to detect the stone in the living kidney than when hardened by keeping.

Mr. Morris, in reply, said that his remarks would be limited to the kind of incision required and as to the period for surgical intervention. The points raised by Mr. Thornton really amounted to three:—1. That by the abdominal method the kidney which contained the stone was not likely to be overlooked; 2. That a kidney was not likely to be cut into when it did not contain stone; and 3. That the lumbar operation was often followed by a tedious recovery. As regards No. 1, he would say that both things might happen. In the kidney which he had shown last week no one could possibly have detected a stone in it. He thought nothing could be claimed for the abdominal incision as regarded certainty, and so far as the healing of the lumbar incision was concerned, in many of the cases operated on, no discharge of urine had taken place. In a case he had recently operated on, within a fortnight of the operation all the urine passed away by the urethra. A great point of importance was the diagnosis. If the physicians would assist in finding out a means of knowing when there was and when there was not a stone, they would be doing public service. When, with symptoms of stone in the kidney, no stone was found, it would be well to investigate the condition of the prostate in the male and of the ovary and tubes in the female. With regard to Dr. Burney Yeo's remarks, it was a very difficult question to answer. He would suggest that if the patient had been to Contrexéville and taken twelve pints of water daily for a fortnight and was no better, then the assistance of a surgeon might fairly be called in. In conclusion, he thought the needle a very valuable instrument of diagnosis.

The papers which were to have been read were postponed to next meeting owing to the lateness of the hour.

LIVING SPECIMENS.

Case of Sporadic Cretinism, exhibited by Dr. A. H. Robinson.

Case of Removal of Renal Calculus, by Mr. A. Pearce Gould.

Saturnine Cachexia and Gout, exhibited by Sir Dyce Duckworth.

Tubercle of Palate and Larynx, by Mr. H. S. Clutton.

Case of Rheumatoid Arthritis in a lad, exhibited by Mr. Sidney Jones.

Curious Cutaneous Infiltration, shown by Dr. Fowler.

ACADEMY OF MEDICINE IN IRELAND.

Obstetrical Section.

Meeting held Friday, Jan. 7, 1887.

Dr. More Madden in the Chair.

OVARIAN TUMOUR.

The President (Dr. A. V. Macan) exhibited part of an ovarian tumour which had been developed between the layers of the left broad ligament. On opening the abdomen the tumour came into view. It was punctured, and a large quantity of fluid escaped, and then the tumour partly collapsed; but he found it impossible to pull it out. He found that it extended along the uterus to the iliac region, and filled the whole of the broad ligament. It seemed to be unilocular, and therefore he only removed the part of it which he now showed, leaving about a third of the tumour behind. He removed the peritoneal covering and tried removal by enucleation; and in some places it gave way easily enough, but afterwards he came to adhesions which rendered that mode of enucleation impossible. The woman had hardly any rise of temperature until the second or third week after the operation, when she had a slight rise of temperature. The woman was now apparently quite well.

The **President** further exhibited specimens of ovaries removed for menorrhagia, due to fibrous tumours.

The **President** exhibited a fourth specimen of a retro-peritoneal tumour which he had removed by laparotomy. On examining her uterus he could not at first find that anything was wrong, but she complained of pain in the abdomen so violent that she said she would rather die than endure it. On further examination he found that the uterus was retroflexed, and that there was something on the top of it; but having made an enlarged incision he got at the tumour, which was behind the intestines and peritoneum and he had great difficulty in removing it, which he did by enucleation.

The President, Dr. A. V. **Macan**, then took the Chair, and

Dr. **More Madden** read a paper on

THE TREATMENT OF VAGINISMUS,

which he defined as excessive sensibility of the vaginal orifice and adjacent parts, attended with such spasmodic contraction of the sphincter vaginæ as to form an impediment to marital intercourse. This, he believed, occurred chiefly in patients of a hysterical temperament, and was generally occasioned by neuromata, confined to the parts supplied by the superficial perinæal branch of the pudic nerve. From clinical experience, he could vouch for the possibility, in many cases, of relieving the most intense dyspareunia thus caused, without any operative interference beyond the forcible dilatation of the vaginal canal and stretching the pudic nerve implicated by the disease. The method of effecting this was detailed, and the writer, at the same time, laid stress on the importance of conjoint employment of that topical and general sedative treatment which is indicated in these cases, as in all other local manifestations of constitutional, nervous, or hysterical disorder. In some instances, however, these failed, and we must then fall back on Sims' or Emmet's operations for the cure of vaginismus, the indications for which were referred to. In conclusion, Dr. More Madden pointed out that it sometimes happens that even in cases of vaginismus, so intense as to render complete marital intercourse impossible, the disease is not necessarily a barrier to impregnation. Thus in one instance under his observation, so extreme was the local hyperæsthesia as not only to prevent the possibility of complete cohabitation, but also to prevent the patient submitting to any local treatment for relief of the morbid condition. Nevertheless, conception occurred, and he subsequently was called in to deliver her at full term, and in doing so was obliged to incise the still unruptured hymen by which delivery was obstructed.

Dr. **Frazer** said he could confirm the remark as to the possibility of pregnancy occurring without vaginal intercourse.

Dr. S. **Mason** said a little rest, and painting the orifice with nitrate of silver, were sometimes very effectual. It was not always necessary to remove the hymen; but when that operation was done it was always well to make a lateral incision in order to expand the orifice.

The **President** said he had met only a few cases of vaginismus. As well as he remembered his reading on the subject, there were two clases of cases—viz., one in which there was some local cause for the trouble, and the other in which the most careful examination could detect no local cause. In the latter class the cause was nervous; and whether excision of the hymen would cure it was doubtful.

Dr. **More Madden**, in reply, said the main features of his treatment in such cases were rest, dilatation, and nerve stretching.

CASE OF PORRO'S OPERATION FOR RUPTURE OF THE UTERUS.

Dr. S. **Mason** read a paper on a case of rupture of the uterus, of which the following is an abstract:—On Nov. 5, 1886, a patient was admitted to the labour ward, Coombe Hospital, who had been in labour with her third child for more than three days. Her two previous labours had been difficult and tedious, the child in each case being still-born, though labour had been completed by natural efforts. A clear history could be obtained of the uterus having ruptured twenty-six hours before the patient's admission to hospital. On opening the abdomen the child was found lying directly behind the abdominal wall and was easily extracted by traction on the lower extremities; the placenta was in the right lumbar region, surrounded by blood and meconium, and the uterus was situated posteriorly, small, and well contracted, and in its lower part was a tear extending completely through the cervix. The uterus was then removed, the pedicel formed by the cervix being secured by a Keith's clamp and a transfixion needle, the abdomen being closed by silk sutures. The patient rallied well after the operation, and seemed to be progressing favourably for about ten hours, when she suddenly commenced to vomit and died. *Post-mortem.*—Signs of recent and extensive peritonitis were found in the abdominal cavity. The portion of uterus enclosed in the clamp was torn through to the lower extremity of the anterior lip of the cervix. The bladder was uninjured. The pelvis was that described as the oblique pelvis of Nægelé, complicated by projection downwards and forwards of the last lumbar vertebra.

Dr. **Smyly** said the great difficulty with which Dr. Mason had had to contend was the poisoning either of the uterus or the peritoneum. To his mind, the great objection to bringing the child back was that it rendered the cleansing of the uterus and perinæum impossible if either had become infected. There had been, in Dr. Mason's case, a considerable lapse of time since the accident had occurred, and the child had died; the escape of gas from the abdomen proved that the uterus and peritoneum had been poisoned. Therefore practically, he believed, the case was a hopeless one, but the uterus might have been poisoned without the peritoneum becoming poisoned. Members were aware that Schrœder had performed Porro's operation in a different kind of case from the present—namely, in order, to remove a uterus which had been infected by a portion of the placenta having been left in by the midwife, the doctor not having been sent for until a considerable time after delivery. In that case the portion of the placenta was found to be completely decomposed, and the operation saved the woman's life. Dr. Mason might have lost his patient by performing Sanger's operation instead of that of Porro.

The **President** observed that so far as Porro's operation could be considered, in itself it seemed to be a very simple one. The indication for performing it seemed to be that such infection existed, that it would be a good thing that the woman should be made incapable of bearing children. On the other hand, if the peritoneum was not infected, Sanger's operation was to be preferred. It was also preferable, on the ground that it left the woman capable of bearing children; and as regarded the comparative mortality after the two operations respectively, it has been made by the new improvements, including those in Cæsarean section, almost the same. How to ascertain whether the uterus was infected or not was not a simple matter. In rupture of the uterus, where the child had been removed in tolerably quick time, the cases ought, generally speaking, to turn out tolerably well.

Dr. **Mason**, in reply, said the woman's pelvis was extremely small. The President had summed up the comparative advantages and disadvantages of Porro's and Sanger's operation. If any great time had elapsed after delivery, Porro's was the better; but where the rupture was very recent, the probabilities of recovery were greater with Sanger's operation.

The Section then adjourned.

◆

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Meeting held Feb. 3.

Dr. **Cleaver**, President, in the Chair.

GOITRE.

Mr. E. Barber introduced a young man, æt. 20, with a large goitre. It had been gradually growing for the past twelve months, giving rise to considerable dyspeptic and respiratory trouble. The swelling was bilateral, and when measured at the time of exhibition, it measured 16 inches round the neck. Under syrupi ferri iodidi in half drachm doses three times a day considerable improvement took place. A month ago the swelling was so great the patient was compelled to have a loop to his collar; he is now able to fasten it without resorting to the loop, and in every respect his health has improved and the goitre much reduced in size.

EXPERIMENTS WITH STETHOSCOPES.

Dr. **BARTOLOME** showed a variety of stethoscopes, and made a few remarks relative to the results he had attained with each. Some of the stethoscopes were turned hollow, and some solid, out of the same piece of ebony, so that with the exception of being hollow or solid, there was no difference between them. The hollow were decidedly the best. He had also tested india-rubber tubes as the conducting media, and contrasted them with others made with solid rubber. The tubes were the best, though not very satisfactory.

THE REMOVAL OF FOREIGN BODIES.

Dr. **CLEAVER** related the case of extraction of a halfpenny from the œsophagus of a child, æt. 3, twelve days after it had been swallowed. The child had swallowed the coin whilst playing, and on being called in, Dr. Cleaver could discover no symptoms of œsophageal obstruction. Fearing copper-poisoning, treatment was adopted to counteract such a result. Next day the child seemed quite well, and was playing about as usual. Watching the child carefully, Dr. Cleaver thought he noticed a peculiarity in the child's manner of swallowing, especially when swallowing his own saliva. Making a digital examination, he thought he could feel the edge of the foreign body, but efforts then made failed. Subsequently, after repeated attempts, the coin was secured and withdrawn with the aid of a long pair of curved forceps. The case shows the absolute necessity of a careful search being made in all cases, even when there are no symptoms indicating the presence of a foreign body. The halfpenny in this case lay across the œsophagus, its head and tail pointing anteriorly and posteriorly, and its edges right and left; its location was about on a level with the second rib.

Dr. **BARTOLOME**, in the course of some remarks made upon Dr. Cleaver's case, related how he was once asked by one of his colleagues to make a rectal examination, and to say what he thought the foreign body was which was present. On passing his finger up the bowel it came in contact with some sharp points, which proved to be the prongs of a fork which had been swallowed some time before by the patient. Colotomy was performed, and the fork removed successfully.—He also related the case of a girl who had swallowed a pin. No medical man could discover its presence, and the girl was in despair and threatened to drown herself. Dr. Taylor, of Hathersage, under whose care she fell, bethought him of a little girl who had a very small hand and arm, with long taper fingers. He got her to pass her hand down the œsophagus, with the result that she discovered and withdrew the pin. Had she been able to do the same for the man colotomy might have been dispensed with.

SOME FORMS OF DISEASE PECULIAR TO AND FREQUENTLY MET WITH AMONGST WOMEN.

Dr. **GWYNN** read a paper on this subject, recommending erasion of the canal of the cervix in chronic endocervicitis, prior to the application of caustics. He also dwelt upon the various approved methods of treating flexions and versions. In the case of flexions he pointed out the necessity for fixing the cervix, while at the same time rectifying the flexion, a double result, only procurable by using stem-pessaries fixed in a diaphragm. He next drew attention to his belief that cases of chronic pelvic peritonitis were much more frequently met with than is usually supposed, and were often overlooked. He related some cases illustrating this, in one of which, after many attacks of a mild nature over a period of three years, the patient at last succumbed to a severe attack. In this case a post-mortem revealed pathological conditions the result of chronic inflammation of very old standing.

The President, Dr. Martin, Dr. Dyson, and Mr. Reckless took part in the discussion.

Mr. **FRANK HARRISON** exhibited a number of dental abnormalities in the form of teeth—(a) in the roots of upper incisors and canines; (b) honeycombed teeth; (c) syphilitic teeth; (d) supplemental cusps and roots of teeth; (e) dilaceration; (f) germination. Also typical cases of—(a) absorption of roots of teeth: 1, front; 2, premolars; (b) caries in old bone frames; (c) enamel odontome; (d) exostosis of roots; (e) teeth causing difficult extraction; (f) irregularities in the number of permanent teeth; (g) salivary calculus, and a lower dentine embedded in it; (h) permanent premolar removed with temporary molar, &c.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 16, 1887.

THE ETIOLOGY AND TREATMENT OF FEEBLE-MINDEDNESS.

OUR readers will doubtless have perused with interest the reports which have appeared in our columns of Dr. Langdon Down's Lettsomian Lectures on the causes and treatment of feeble-mindedness in children. Dr. Down is a veteran student of feeble or enfeebled minds, and has a rich store of experience to draw upon, in supporting and explaining his conclusions. He carries, it is true, the structural peculiarities which he has observed in the build and features of idiots, a step further than, without the advantage of his experience, one would be inclined to go. Notwithstanding its attraction, it is an argument which readily admits of the *reductio ad absurdam*. True it is, and must be, to a certain extent, in the same way as phrenology, but like this science, requires to be kept well in hand if we are not to be misled. A much more satisfactory classification than the one based on ethnical distinctions is that which Dr. Down adopts of dividing feeble-minded children into congenital and accidental.

Apart from these two categories there are a large number of children whose intellectual development was arrested or modified at dentition or subsequently. This class, which Dr. Down classifies separately as "developmental" constitute a very important variety. Their nervous organisation is possessed of but little stability and readily loses its equilibrium. They are the cases which break down by over-excitement in baby-hood and by "over-pressure"—that is, pressure too great for them with inherent want of stamina at second dentition and puberty. These cases are the more important seeing that with due care, they may in many cases avoid the breakers on which their intelligence would founder. The "accidental" variety, whose condition is due to traumatic lesions, inflammations, &c., are so far peculiar that they offer none of the physical aspects of feeble-mindedness; there having been nothing during the period of intra-uterine life to arrest the evolutionary stage and stamp its impress on the body or features. These children, though offering a striking contrast to the congenitally feeble-minded children, are less amenable to training, a damaged brain not being so susceptible of development as an ill-developed brain. The lecturer took occasion to insist on the fact that mere size of brain was absolutely without significance, and this can be readily admitted. Arching of the palate is a sign of great weight in the diagnosis of *congenital* idiocy; in these cases too, common and special sensation are both obtuse, the development of the muscular system is delayed and walking is late to be acquired.

In his second lecture, Dr. Down took up the etiology of the "accidental" feeble-mindedness. While instrumental interference *might* have caused about 9 per cent. of the cases, in more than 20 per cent, there was a history of suspended animation or a hitch of some kind at birth. Prolonged labour and consequent pressure, was a much more potent factor than mechanical injury from the use of instruments. Sunstroke, the administration of opium and sexual excitement wilfully induced by nurses to keep their charges quiet, are all responsible for a part of the number, but meningitis doubtless leads to a large proportion of the cases.

The etiology of congenital feeble-mindedness is a much more recondite question. In many cases it is due to simple degeneration which is accentuated in successive generations until the climax is reached. Many suggestions have been made, as to disparity of age in the parents, marriages of consanguinity and the like, but the result of a large series of observations tends to negative any such hypotheses. If hereditary taint exist, intermarriage may be expected to intensify it, but will not produce it *per se*. It is unsatisfactory to know that feeble-minded people are very prolific but it is only in accordance with the fact taught by observation that in highly developed races, prudence and foresight tend to check over population, the want of which in less educated or less developed races, conduces to a reckless and improvident use of the reproductive organs.

The influence of maternal health on the production of feeble-minded offspring is very great. Violent emotions, chorea, epilepsy, and eclampsia may be of the gravest import to the offspring. Periods of political excitement, wars, &c., all increase the roll of feeble-minded children, and the effect in certain instances has been demonstrated with almost mathematical accuracy. Severe emotional disturbance even in the father may lead to a similar result, but apparently with less certainty. Alcoholism as might have been expected, is responsible for a very tangible share of mental and physical degeneracy, and in Norway after the removal of the spirit duty, insanity increased 50 per cent., and congenital idiocy 150 per cent. Syphilis is not, it appears, an important factor, but phthisis exercised a very marked influence, existing as it did in 25 per cent. of the fathers and 20 per cent. of the mothers.

The influence of trades and professions is possessed of more than usual interest. Out of 400 cases with fair social antecedents, he found that 75 per cent. were the children of merchants, county gentlemen, officers in the army and navy, and members of the titled aristocracy; no less than 25 per cent. were the children of members of one or other of the three learned professions. It is comforting to know that while three per cent. were the offspring of lawyers, and four per cent. of members of the medical profession, no less than 18 per cent. were the children of members of the clerical profession. On the other hand, the legal profession gives birth to 11 per cent. of the present men of eminence, the medical to nine per cent., and the clergy to only four per cent. The lecturer emphasised these figures by saying that in his opinion it was not "mere accident, but a process of natural selection." We must leave our readers to draw their own conclusions from these figures and remarks; the question is well worthy of consideration. With the circumstances before us which preside over the production of developmental feeble-mindedness, it is not surprising that illegitimacy should be a common cause of idiocy. The physical suffering and mental anguish of the unhappy mother reflects itself on the offspring. Since the development of intelligence is dependent on the reception of impressions from without, the inability to receive such impressions naturally tends to prevent it, as in blind and deaf children.

Coming to the vexed question of the higher education of woman, Dr. Down ruthlessly cuts away the sentimental considerations which have been allowed to pass current for argument. If there be one thing more than another, he says, about the production of idiocy, it is the danger which arises from the exclusive cultivation of the purely emotional side of a woman's nature. Intellectual pressure during developmental crises is to be avoided as well in girls as in boys, but education alone can raise women above being the mere frivolous toys of the hour, and make them companions and helpers, as well as mothers, of men. The hint the lecturer threw out as to the desirability of seeking alliances from a healthy stock on either side, is one pregnant with meaning, but is one which unfortunately is not likely to be generally adopted. In the selection which is the prelude to marriage, considerations quite foreign to physiological considerations have the greatest weight and affect the scientific man in common with his less cultivated brothers.

The problem of moral insanity, as exemplified in individuals who are unable to rise to a conception of the duties as well as the pleasures of life, is one which is brought home to all of us. The lack of self-control and the sense of responsibility presents itself in every conceivable gradation of intensity and its subjects are the most difficult to treat. Education, specially devoted to the weak side of the character, is here of particular value. It is to be supposed that while this feature is one which readily responds to cultivation, it is one which will flourish only under certain conditions and promptly withers and dies under an inclement sky.

In conclusion, Dr. Down deals with the pathology and treatment of this distressing class of affections. It will suffice to say that in several categories of cases the happiest results follow careful and patient training. The greatest honour and credit are due to men who have voluntarily given themselves up to this irksome and often ungrateful task. Nothing assists so much in ameliorating the fate of these unhappy beings, as the proper understanding of the phenomena which underlie their condition, and in this department Dr. Down has done work of an extent and value which it would be difficult to over-estimate.

◆

"INSPECTION" AS A CHECK ON EXAMINATIONS AND STUDIES.

ONE of the chiefest duties of the Medical Council at its meeting of the present week will be to consider the method to be adopted to discharge the function of inspection which devolves upon them under the new Medical Act. The only proviso on the subject which that Act contains is that "such number (of inspectors) as may be determined shall attend all or any of the qualifying examinations," for the purpose of "maintaining the standard of proficiency" of the practitioner. But, when it is considered that this inspection is the only means which the Act provides to protect the profession against the lowering of the educational standard by any licensing body, it will be readily understood how important it is that it shall be active, genuine, and reliable.

It is because we apprehend that a vigorous effort will be made to reduce the supervision to the level of a sham that we now call attention to the matter. We have good reason to believe that certain examining bodies are in hopes that they will be able to get the inspectorial function relegated to local men who are in their interest, who will put in an appearance at their examinations, give no trouble by suggesting a high standard of test, make no complaints about the sufficiency of the method adopted, and will eventually report a series of laudatory platitudes, in the manner of the Visitors appointed by the General Medical Council some years ago. We earnestly hope that the Council will not be induced by any means to localise these appointments, but that they will select men independent of the interests of the bodies on whose examinations they are to report, experienced in education and examination, and sufficiently stiff-backed to speak without hesitation the opinions they may form. Such men will, of course, cost a good deal of money, for, if the inspection is to be thoroughly done, they will be able to do little else; but it is well worth while to be extravagant in an item of outlay so indispensable to the working of the new system. We trust also that the inspectors who may be appointed may have knowledge of the methods of teaching and examination of the present day, and that the duty of criticising examinations may not be confided to those who are conversant only with the system of thirty years ago, however eminent they may have been at that date.

The inspection of schools and hospitals which has already received the approval of the Council will be again brought to their notice, by a resolution recently adopted by the Irish Branch Council, strongly favourable to such supervision. Dr. Haughton will, we expect, urge the Council to take steps to put this inspection in force without delay, and we earnestly trust that his representations will be listened to. At the present moment the Council is in occupation of a curious fools' paradise. It has employed itself for years in determining the nature and extent of the medical studies in hospital, lecture room, dissecting room, and laboratory, which the student shall be required to give proofs of, and the licensing bodies have, with equal elaboration, formulated the details of their curricula, specifying with exactness the number of months attendance which, at a minimum, will be accepted. But it seems that both the Council and the Colleges have failed to realise the fact that all this educational perfection exists, to a great extent, on paper only; that the certificates of study which the candidate produces as his title to be examined may be, and in innumerable instances are, simply receipts for money paid to the vendor of the certificate, and do not express or imply any study pursued, or any knowledge acquired whatsoever. The Council is possibly not aware that there are centres of instruction, more than one, in which the student can purchase any reasonable quantity of proofs of study as readily as he would a pair of boots, and can present these papers to his examiners with the satisfying certainty that no questions will be asked, that no doubts as to the *bonâ fides* and educational value of these papers will be even hinted at, and that he will be passed on to his examination just as smoothly as if he had really given himself the trouble to attend all the lectures, hospital visits, and dissections for which he has been certified.

It is the simple fact that no student need fulfil the whole or any part of the educational study which the Medical Council and the Colleges profess to require, if he does not think it worth his while to do so, and that a large majority of the students who pass in certain centres of education and examination are admitted upon certificates of study more or less of which are audaciously false.

Now there can be no excuse for such a state of things. A single inspector of teaching, at a salary which might be very moderate, because his duties would not require high attainments, would at once bring these abuses to an end by walking—at erratic periods—into schools and hospitals, counting the classes at lectures, examining the roll of attendance or the students' signature book, and reporting to the Branch Council what he saw. Before a month of his functions had gone by the signing of a dozen names in the attendance book, or the answering of several names at roll-call by a single student, would cease, in presence of the certainty of detection. The lecturers would find themselves compelled to give the number of lectures devolving upon them; all the other time-honoured dodges of medical teaching would be brought to a precipitate conclusion.

It remains to be seen whether the Medical Council is really in earnest in formulating and requiring a curriculum of medical study, for, if it is, it cannot escape from the necessity to give effect to the resolution of the Irish Branch Council. If it is not in earnest, and has only desired to make a paper scheme of education, then we think it would be better to sweep away all such imaginary obligations on the student, and to make examination the sole test, than to be pretending to enforce studies which, in point of fact, are in many cases entirely voluntary.

THE CHOICE OF INCISION IN NEPHROLITHOTOMY.

THE discussion which took place at the Clinical Society on Friday evening last, on the papers read at the previous meeting on Nephrolithotomy, and which is reported in our columns, was of great interest. From it we are enabled to gauge the wonderful advances which have been made in this in common with other departments of abdominal surgery. The ease and certainty with which the kidney may be cut down upon, examined, and if necessary, emptied of calculi, gives a favourable impression of what can be achieved with a competent anatomical knowledge backed by care and scrupulous cleanliness in operative details. Renal calculus was formerly a malady the only treatment for which was palliative, and if the patient recovered, it was by sheer good fortune, and due to no interference on the part of his medical advisers. At present, if the symptoms are severe, and ordinary treatment unavailing, the surgeon promptly cuts down on the affected organ, palpates it thoroughly, and if necessary, progs it through and through with an exploring needle to ascertain the presence of stone, which, if found, is removed. The risk to the patient is comparatively small, especially if the operation has not been postponed until the health has suffered.

That is the bright side of the picture, but it would be unfair to allow it to be supposed that the procedure is uniformly successful. Numerous pitfalls await the surgeon, to which even the most cautious occasionally succumb. The question of diagnosis is one which is naturally of extreme and primary importance. Not only is it by no means easy to affirm the existence of renal calculus in many cases from the symptoms, but, curiously enough, these symptoms often indicate the wrong organ, and so the right kidney may be cut down on, while the left is at fault, or *vice versâ*. Further, it is often difficult and even impossible to detect a stone even when present, or a small stone may escape notice which continues to give rise to the same distressing symptoms To these must be added the fact that a kidney may be packed with calculi without causing any characteristic symptoms, and on the other hand, the symptoms may exist without the stone. On the whole, therefore, it is no matter for surprise to be told that a great number of kidneys are cut down upon and examined with a negative result.

The point at issue between nephrolithotomists is as to the best method of getting at the kidney, whether by a lumbar incision or from the front. Mr. Knowsley Thornton advocates a combined method, in which the diagnosis is made from the front, and supplemented if necessary by a lumbar incision for purposes of removal of calculus. By these means, which Mr. Thornton has employed with great success, it is claimed that in case of error of diagnosis as to the particular organ affected, the other can easily be reached by one and the same operation. This view did not commend itself to Mr. Henry Morris, who preferred the lumbar incision. This gentleman was somewhat sceptical as to the advantages claimed for the double operation, and pointed out the difficulties which under any circumstances, surrounded a diagnosis. It is all very well for Mr. Thornton, who lives on terms of the greatest intimacy with the peritoneum, to allude complacently to the ease with which accidental injury of that structure can be seen and attended to. All surgeons are not on the same happy terms, and would prefer to avoid adding to the severity of the operation, unless some very tangible advantage accrue therefrom.

There is still ample scope in the surgery of the kidney for further research. Many questions and symptoms call for further elucidation, and this they will doubtless obtain at the hands of those enthusiastic surgeons who—as one of the speakers put it—yearn to perform the operation. The operation has now acquired a legal status, offering, as it does, the chance of more or less permanent relief to patients formerly condemned to purchase immunity from pain by constant recourse to narcotics, and whose sufferings, in the majority of cases, only ceased with death.

◆

WHAT SHALL WE DO IN OUR HOLIDAYS?

THE farewell lecture delivered by Sir Edward Sieveking, M.D., to the students of St. Mary's Hospital, a report of which will be found elsewhere in our columns, is interesting, were it only as marking the conclusion of Sir Edward Sieveking's active career. Not that this veteran physician retires from service altogether, but, as he observes, an epoch arrives when man requires rest and relaxation. Up to a certain age this want is supplied by the annual holiday which forms or should form an integral part of the hard-worked professional man's existence. As years pass by, however, the stock of vital energy gets lower, and the recuperative powers are weakened, and the whole tenor of existence has to be modified. The M.P. must accept the Chiltern Hundreds, and the active practitioner reserve himself for consulting practice. After thirty-six years of interesting and loving labour at St. Mary's Hospital, Sir Edward now finds this period upon him, and wisely relinquishes the more active duties of his post to younger men, but his experience and knowledge will still be available to those who don his mantle.

The subject of this valedictory lecture is ostensibly the disposal of holiday time, and some very practical hints are given as to the best way of employing this period of *désœuvrement* to the best advantage. The holiday should not be spent in lotus-eating, but the invigorating effect of change of scene and thought should be assiduously cultivated. The particular method of so doing must necessarily be left to individual idiosyncrasy, but the full benefit of the change is only obtainable on condition of a lively appreciation of an altered condition of existence.

The lecturer, however, soon passes on to a consideration of the influence of climate, and his remarks may be read by everyone with profit. Mere change of locality or climate in the treatment of disease is not only apt to be useless, but may be positively injurious, unless due consideration be given to the requirements of the patient. This is a point to which far too little attention is paid, and climatic treatment is often worse than empirical. Some very interesting and useful details are given concerning the watering-places of Great Britain, many of which deserve more favour than they get in these days of rapid travelling. The lecturer is evidently quite familiar with the vast therapeutical resources which we possess in the various home waters and health resorts, and his advice would be valuable on this subject.

The sea, the sea, the bright blue sea, is doubtless a valuable resort for tired and fagged organisms, but its frequentation is attended with certain drawbacks which militate against its universal use. Several conditions must be fulfilled before patients can safely be recommended to take a sea-voyage for the sake of its invigorating and tonic properties. The itinerary which the lecturer has sketched for visiting the Continental watering-places errs perhaps on the side of comprehensiveness, although of course the entire series need not of necessity be exhausted at one fell swoop. The eminently practical nature of the advice which he gives shows that the lecturer has given no small amount of attention to the comfort as well as the treatment of his patients. It cannot be too strongly insisted upon that in order to give patients the full benefit of whatever locality they resort to, due provision must be made for comfort. The most healthy place may be unproductive of good results if hotel accommodation be insufficient, if sunlight be at a premium, or if the scenery be dull and monotonous. The patient requires to be amused as well as treated, and there is every inducement for a medical man to render himself personally acquainted with the sites before subjecting his patients to the fatigue of a long voyage.

In conclusion, we can only express the cordial wish that Sir Edward Sieveking may enjoy for many years the comparative repose of a purely consulting practice—the *panis bene meritorum* to which his many years of service entitle him.

◆

HER Majesty the Queen has intimated her intention to become a patron of the National Hospital for the Paralysed and Epileptic (Albany Memorial), Queen Square, and to send a donation to its funds.

Notes on Current Topics.

National Dress Reform.

THE question of female dress reform is periodically brought to the front by enterprising ladies whose affections are pretty equally divided between their husband and the "divided skirt," and who are particularly anxious to generalise the use of the latter; the discussion is not devoid of interest even to those whose sex renders the matter a purely scientific consideration and some insight may be gained into the construction and inconveniences of garments, the nature and even the name of which has hitherto been a mystery. One lady volunteers the information that she has long given up petticoats in favour of Turkish women's trousers or knickerbockers, the advantages of which, she says, are obvious though hidden. It is not easy at a glance to ascertain exactly on what grounds this particular reform is called for. It may be conceded without a murmur, that women as a rule, notwithstanding the employment of an incredible allowance of textile fabrics, generally fail to protect the really delicate portions of their bodies, such as the lungs, while they pile up garment upon garment around the pelvis, which stands in no particular need of protection. We would willingly sacrifice the artificial modifications of the human figure which women adopt, upon the altar of hygiene and good taste, but further information and details will be required before we can endorse the advantages claimed for the divided skirt. We gather from what has been written on the subject, that this skirt does not necessarily give the appearance of being "divided against itself," and has nothing in common with what used to be called the "Bloomer" costume; its want of unity only becoming apparent under a high wind. It is alleged to be warmer, more comfortable and more becoming (?) but, so far, a singular and indomitable prejudice has prevented its coming generally into use; although hygiene and preventive medicine have been press-ganged into the service of the reform. It is a question which, after all, the ladies may be left to decide on its merits. In return for this neutrality, we only ask that they shall abstain from irrelevant and disparaging remarks as to the shape of the "male hat" and evening dress. One lady has the audacity to suggest that if the trousers are buttoned *outside* the waistcoat, much greater liberty of muscular action would result, but such remarks cannot be considered otherwise than impertinent.

Teetotallers Beware!

A QUESTION was asked in the House of Commons of the Secretary of State for India as to the truth of the report that eight men had been put in prison in the presidency of Bombay for having endeavoured to forward the temperance cause by making abstinence a rule of their caste. A proclamation is further said to have been issued by the Government to the effect that "if anybody by threats of violence or otherwise, endeavoured to hinder others from purchasing or drinking liquors," he would render himself liable to criminal prosecution. The official answer, *secundem artem*, was ambiguous, and so far unsatisfactory. It was, however, pointed out that a similar liability to prosecution actually existed in England. This being so, our friends the teetotallers may consider themselves very fortunate in being at large, for, even if they have not endeavoured to prevent people drinking by violence, they have certainly done so "otherwise." It seems incredible that any responsible authority could have issued such a proclamation, and if the fact is ascertained to be true, the perpetrators of the stupidity deserve to be held up to the derision which they would have richly merited.

An International Congress on Cremation.

An International Congress of societies and persons interested in cremation is announced to take place at Milan in September of this year. The programme of the Congress comprises (1) a general statement of the progress of cremation among different nations; (2) a proposal for constituting an international league of cremation societies; (3) a proposal for international legislation, regulating the removal of bodies from one country to another, and the methods of cremation and conservation of the ashes from the point of view of public hygiene and legal medicine. There will be an exhibition of models, plans, and designs, books, &c., relating to and bearing on cremation.

Safety of Places of Public Entertainment.

A Bill has been introduced by the chairman of the Metropolitan Board of Works, Sir J. McGarel-Hogg, for the purpose of obtaining powers to inspect theatres, music-halls, &c. It provides for the annual inspection of the buildings which are comprised in the Act, with the view of ascertaining that adequate arrangements exist for public safety, in case of fire or panic, and no place of public entertainment will be allowed to open without a certificate to that effect. Should the Bill become law, a great step will have been taken in the interests of public safety; it is a scandal and a disgrace that such provisions still remain to be enacted, and the fact does not reflect credit on the authorities hitherto responsible for this department.

The General Medical Council.

The General Medical Council as reconstituted under the Medical Act of last session, met for the first time yesterday (Tuesday). The Council have some very important matters to discuss, and there seems every probability that the additional members will take an active part in the business of the session. We shall give a report of the proceedings in our next issue.

Death During Aspiration.

Cases of sudden death following puncture with an aspirating needle are by no means unknown, but it is as well to bear in mind that they actually do occur now and again. Dr. Reeves, of Ohio, reports a case in which it was deemed advisable to aspirate the liver in a young man, twenty-three years of age. The needle had no sooner been plunged into the organ than the patient's head was drawn to the left, a slight convulsive tremor passed over his features, and death supervened. At the autopsy a large abscess of the right lobe of the liver was found. The right auricle was much distended, but the heart was otherwise healthy. The cause of death was evidently reflex inhibition of the heart's action due to shock. It is possible that had the operation been performed under complete anæsthesia, the unhappy result would not have occurred.

Vital Powers of Natives.

Under this heading a South African contemporary publishes the curious case of a man, aged 35, who had been struck with the pointed end of a pickaxe just above the frontal sinus, in the middle of the forehead. The blow had fractured both tables, and had made a triangular opening in the skull. The base was parallel to a line joining the two eyebrows, and about half an inch above them. When the case was first seen, the fractured portion had been removed, so that a triangular opening was left through which the interior of the skull could be distinctly seen and felt. On inquiry, it was found that the man had suffered a great deal during the first week, but his intellect was bright, after that time the pain diminished and the intellect became more cloudy; several days later, he fell into a kind of stupor and died without proper medical attendance. The natives have in their views of surgery a great love for probing wounds, and the wife in this case had used the wing feathers of a fowl as probes. By stripping off the webs, excepting just at the point of the feather, she had made a most useful instrument for removing any pus from the interior of the wound. Using one of these feathers as a probe, she used to introduce it into the wound, and then by twirling it energetically between her thumb and forefinger, she collected and removed a large quantity of what she considered obnoxious pus. A post-mortem examination being made, it was found that the poor woman in her anxiety for her husband, had removed as pus a large portion of brain matter, in fact had almost emptied her husband's cranium. From the external opening she had drilled a hole four inches deep (in fact as far as she could reach with her feathers), and about two inches in diameter. She had in fact for three weeks made daily attacks on her husband's brain, and had at each attack removed a portion of it, and yet the man survived it. Even the vital powers of natives have a limit, however, and the man ultimately succumbed.

The Dublin National Children's Hospital.

This very stirring little institution has broken new ground in a very surprising way. It began—as our readers may recollect—not so many years back, in two rooms of a house located in what one might call one of the slums of Dublin, its speciality then being orthopœdy. Having established, notwithstanding its humble surroundings, somewhat of a name for itself, it flitted to more commodious and respectable premises in Adelaide Road, where it opened its doors to all children's diseases, and changed its name so as to indicate that fact. In that situation it acquired so much increased strength that it has now taken a much higher vault towards public estimation. In the first place, it has absorbed the Children's Hospital in Pitt Street, the physician of which, Dr. William Moore, joins its staff, and that institution will be closed in a few days. It has, moreover, purchased for £3,000 the block of houses at 87 Harcourt Street, formerly a famous school, and more recently a convent, which will be capable of accommodating 100 patients whenever the institution can afford to keep that number. Clinical instruction will be given to students not only by Mr. Ormsby, who has been the chief worker in the hospital through all its life, but by Dr. William Moore and Sir William Stokes. All admirers of pluck and enterprise will join us in congratulating the Hospital on its new departure.

The late Professor Schroeder.

No one who saw the late Professor Schroeder a few months ago apparently in the bloom of health and in the prime of his manhood could have thought for a moment that the grim destroyer was so near, and that in the course of a few short weeks his earthly career would be closed. But so it is. At the Berlin meeting of the Deutsche Versammlung der Naturforscher & Aerzte he was one of the most active members of the Gynæcological Section, ever ready to take his part and to illumine from his vast experience and extensive knowledge whatever topic might be before it. His fame was not confined to Germany, but was world-wide. His name is almost as familiar in English medical literature as in German, and the most scientific work on obstetrics by him which has long been translated into English will ever keep it in the foremost ranks of science. A contemporary says he was present at the Liverpool meeting of the British Medical Association in 1883. This is a mistake; he was not present, but he sent, however, a paper to be read in the Obstetrical Section. Although a comparatively young man at the time of his death—he was only 49—he had long occupied the foremost position in his branch of the profession in Germany, the Professorship of Gynæcology (including obstetrics) in the University of Berlin, and the Directorship of the University Frauenklinik, and from his Sovereign he had received the title of Geheimer Medizinal Rath (Privy Medical Councillor). In person he was tall and massive in build, and in his manner there was certain massive impassiveness that could not fail to strike a stranger. In speaking he was fluent, never at a loss for the proper word or thought, but deliberate withal; his voice was deep and low, and a marked character was given to his speeches by a peculiar upward inflection of the voice before every pause, not unlike what one hears sometimes in clergymen reading prayers, but very rarely met with on other occasions. In private as well as public life he was much respected and beloved by all who knew him, and even strangers felt themselves instinctively attracted by his presence. Since Frerichs and Cohnheim, no German has left by his departure a larger gap in the ranks of the profession.

The Hospital for Women, Liverpool.

The latest phase in the controversy at this Hospital is the retirement of six members of the committee in consequence of the voting at the annual general meeting on the 3rd inst., referred to in our last issue. As the vote could only be taken as a condemnation of the policy favoured by a majority of the committee, the seceders have adopted the only course they could with dignity to themselves follow, viz., withdrawal from the management of an institution with the views of whose governors theirs were clearly at variance.

Regimental Medical Officers.

General Sir Donald Stewart, when addressing the young surgeons at Netley on a recent occasion, remarked that "the present system was open to some objection in not providing for a medical officer to be attached to each regiment; it would be advantageous to adopt such a plan, as the surgeons would come to know the men better." In these words this gallant and experienced officer gave expression to one of the strongest reasons which have ever been adduced in favour of the regimental, as opposed to what is called the unified medical system in the army, namely, that the surgeons come to know the men better, and knowing them, are thereby placed in a better position to appreciate the extent of the illness, individual conditions and peculiarities of soldiers who "report themselves sick" than can possibly be attained when, as is almost invariably the case under the present system, surgeons and patients are strangers to each other. The fact so often adduced in respect to physicians and patients in civil hospitals being strangers to each other has no relation to military life, for reasons that are sufficiently well known in the initiated. On the score of expense it has been stated that a grant of £40,000 additional to the present would be required to reintroduce regimental medical officers. But we venture to think that this sum would be one more of *account* than of actual money. Thus, with regimental medical officers, and regimental hospitals, there was no expense incurred for administration, at the same time that, on home service, the daily pay of the regimental surgeon and assistant surgeon was more than met out of the hospital stoppages of the men. In India, in times of war, every kind of hospital was successfully organised out of the several establishments belonging to regiments. Nor did any hitch whatever occur in their working.

Recent Experiments on the Injection of Bacteria into the Veins.

Professor von Fodor, of Buda-Pesth, communicated in a recent number of the *Deutsche Medizinische Wochensch.* the results of his investigations into this subject. He had shown in a previous communication that hundreds of millions of non-pathological bacteria injected into the blood completely disappeared from it in the course of a few hours. By further experiments he showed that this power of the blood to destroy bacteria was not diminished by a moderate degree of anæmia, but was lessened by dilution of the blood with water, so far that the bacteria were destroyed more slowly and with greater difficulty. Even pathogenic bacteria disappear rapidly out of the blood, for example, typhoid bacilli, which even a few hours after injection are no longer demonstrable in the blood, whilst the animals are in some cases simultaneously infected by the injected material, and die with symptoms identical with those of typhoid. Anthrax bacilli injected in large quantities disappear within four hours, but within from twenty to forty-four hours they again appear in the blood, and the animal dies. In the period in which it is free from bacilli the blood contains, as far as the negative injection experiments show, no material producing anthrax; this is the best proof that it is the bacilli that produce the disease. In the same period, however, in which the blood is free from bacilli, in the internal organs (spleen, liver, kidneys) they are constantly present, from which it is evident that the pathological development of anthrax does not take place in the blood, but in the internal organs. Anthrax is not a blood disease, but the blood is rather the protector of the organism against the pathogenic bacteria. A very small quantity of anthrax material is not lethal, and further, the rapidity with which the disease is fatal is in direct proportion to the quantity of injected material. According to von Fodor, the bacilli injected into the blood are destroyed by it; some, however, reach the organs and there develope. When the colonies steadily multiply in these parts, then the blood, the chemical constitution of which is changed thereby, and is no longer able to destroy the bacilli that are present in it, in this stage bacilli are found in the blood, but the animal is then practically at the point of death, its doom is sealed.

A Steel Fork in the Abdomen.

At a recent meeting of the French Academy of Medicine, M. Polaillon presented a steel fork which he removed by gastric section from the stomach of a juggler. æt. 25. The fork was accidentally swallowed on the 8th of the month, and although he suffered from spitting of blood he still continued his business. Soon, however, he began to experience severe pain in his stomach, and, on applying to Dr. Lavergne, of Luchon, he was sent to M. Polaillon, under whose care he became a patient in La Pitié on the 14th, six days after the accident. The man on admission to hospital complained of pains during fasting, which were lessened by eating, the diminution of pain on eating being explained by the stomach becoming distended by food. Exploration of the abdominal parietes revealed nothing, and examination by the œsophageal sound was equally barren of evidence. M. Polaillon now began to doubt the veracity of the patient, and finally determined to use a magnetic needle to assist his diagnosis. The needle was suspended on a cord, and at once it deflected on being brought in contact with the abdominal walls.

The operation performed was that recommended by M. Labbé. The stomach was easily found and the fork was readily felt through its walls. Three vessels were tied during the operation, and when the bleeding had ceased the stomach was returned to the abdominal cavity. On the morning of the 24th, sixteen days after the accident, the patient was in excellent health.

The Jubilee Festival of the National Hospital for the Paralysed and Epileptic was held on Feb. 9th, and a dinner was given at the Holborn Restaurant, under the presidency of the Lord Chancellor. Sir J. Crichton Browne took advantage of the opportunity to pay some well-deserved compliments to the medical staff of the hospital. There is scarcely a member of the staff whose name is not well and favourably known in the scientific world, and they may fairly be said to be a *corps d'élite.*

Centennial Anniversary of the Philadelphia College.

Early in January last, the College of Physicians of Philadelphia, celebrated the one hundredth anniversary of its foundation, the minutes of the College beginning with the account of a meeting held on January 2nd, 1787, when the institution was organised on a lasting basis. The occasion of the celebration was marked by the presence of a large number of the most eminent and honoured physicians in America, and a very interesting feature of the event, was the delivery of an eloquent and stirring address, dealing with the history and triumphs of the College since its creation, the orator being Dr. S. Weir Mitchell. Among other speakers at the various gatherings held, were Professor Da Costa, and Dr. Stillé, and a number of honorary fellowships were conferred on distinguished members of the profession. A well attended banquet was also part of the proceedings, which were altogether of a very successful character.

Female Medical Students Abroad.

Nature gives, in a recent issue, some interesting details respecting the number of women engaged in the study of medicine at certain European centres of professional education. At the University of Paris, there are at present *in statu pupillari* in this faculty, no fewer than one hundred and eight women thus distributed as to nationality:—Russian, 83; English, 11; French, 7; American, 3; Austrian, 2; Roumanian, 1; Turkish, 1; the greater proportion of Russian students is due to the closing of the Female Medical School, founded a short time ago in St. Petersburg; and it is assumed by M. Beclard, in his report to the Academical Council of Paris, that owing to the fact that the preliminary studies of the Medical Faculty of the University having now been made the same for men and women alike, the number of the latter entering the School will undergo gradual but certain diminution. It is also noted that one lady, Miss Klumpke, has been elected this year, after the annual competition for the post of *interne*, or assistant in the Paris hospitals, she having secured the second place on the list of successful candidates with a total of 27 out of 30 possible marks. The first place was gained by a male student, with 28 marks. At the University of Upsala, there are at present three ladies engaged in the study of medicine.

The Mercer's Hospital Trial.

We recently condemned with all emphasis and in all its aspects, the illusory inquiry by a Committee of the Dublin Corporation into the management of Mercer's Hospital, and the hot haste and liberality with which that Committee applied its coating of white-wash to the institution at the moment when a police inquiry on the subject was coming to a conclusion. That inquiry and report went for nothing with the public, who waited very properly for the verdict of a jury and the opinion of a judge before forming a conclusion as to the merits of the controversy. That verdict has been given—and given in a form which completely exonerates the House Surgeon, Dr. Kennedy, from the serious charge of inhumanity to a dying patient. Not only has Dr. Kennedy been declared not guilty, but both Judge and Jury have emphasised their verdict by declarations that he should never have been submitted to the indignity of such a charge. We congratulate him on so complete a vindication, and we sympathise with him in the misery he must have endured by the pendency of such an accusation. We also felicitate the Mercer's Hospital on being cleared of such an opprobrium, and Hospital managers in general upon the re-establishment of public confidence which such a verdict must bring with it. But while we gladly do the plain justice to Dr. Kennedy of recording the full extent of his acquittal, we ought not to do less than justice to one of the witnesses against him, who, we think, has been maligned by inference if not by words. On the cross-examination of Nurse Whitcross, who had testified as to the treatment which the patient received, it was suggested that her evidence was not entitled to full credit because she was familiar with students to the extent of calling them by their Christian names. A letter was put into her hand commencing "My dear Willie," and, as she was obliged to admit the authorship, the impression was left that she was in terms of familiarity with the accuser of the Hospital, whose Christian name is "Willie." If this could have been proved the cross-examination would have been quite legitimate, but the fact was quite otherwise. The letter in question was, we believe, addressed to a student to whom the nurse was engaged in marriage, and who died in the Hospital a few days before this police-court investigation. If this be true, the familiarity suggested would be quite reasonable, and, as it had no relation whatever to the accuser in the case, would not in the least affect her credibility.

But the question we are concerned to ask is, How it happened that a confidential letter addressed to a student who had died in the Hospital came to be used for the purpose of the legal defence of the house-surgeon? It is certainly not conceivable that it was given to be used for such purpose by the deceased, nor is it to be believed that any member of his family would authorise such a use of his private letter. How, then, did the defending lawyer obtain possession of it, and permission to use it for such purpose? The question opens up possibilities of a breach of confidence so foul as not to be described in moderate language; but we presume there is a good answer ready, and we shall be glad to know what it is.

The University of Edinburgh and Professor Rutherford's Explanation.

But for the important letter addressed by Professor Rutherford to our contemporary the *Lancet*, to which our Edinburgh correspondent refers, we should not, for the present, have added more on the disagreeable subject which for some weeks has unhappily occupied the minds of all who have the welfare of our Scotch Universities at heart. The interests of justice and public morality, however, demand something further.

Dr. Rutherford has to inform the professional world that no "gross charges" were brought against his late assistant by him, "nor were illegal charges of any kind intentionally made against him, even by imputation." We are glad that the Professor has come forward to repudiate all connection with the grave charges, not unjustly termed "gross," which rumour, even in metropolitan circles, has associated with his name. The letter is in interesting correspondence with the statement which Dr. Rutherford made to his class, in reply to certain newspaper strictures. We shall be the first to rejoice when we know that the learned professor has completely vindicated his position. While, therefore, it appears difficult to reconcile those statements with the terms of the humiliating apology in which Dr. Rutherford "expresses his deep regret for having charged Dr. Ashdown, both personally and to others, with objectionable manners on some occasions," and admits that there was "no occasion for any such charges," we willingly suspend judgment till the facts of the case are known.

But we demand once more that the matter be looked into with as much expedition as possible. Some one is responsible for the assuredly gross rumours which are floating in the air, and the sooner that responsible individual be brought to book the better for the profession at large and for the University of Edinburgh. If, as is suggested in Professor Rutherford's address to his students, reports are being purposely exaggerated, the perpetrators of so base calumniation must be exposed, and an end put to those black rumours which are casting a shade on the fair fame of the largest of our medical schools. The responsible authorities are, it is to be hoped, in ignorance of much that is freely bandied about at club, after dinner, and even, we fear, in the class room. It is such reports that have stimulated the daily press of Edinburgh to treat the matter with firm hand. Our appeal to the University authorities for a thorough-going investigation has been vigorously backed by the leading newspapers. But, so far, the appeal has met with slight response.

There is yet another tribunal which may feel it incumbent on it to take cognisance of the matter. The General Medical Council is now sitting, and its powers, it may be presumed, extend to the consideration of so grave a matter, implicating the moral value of more than one name on its Register, and affecting the reputation of one of the most important of the institutions which it represents. We commend the matter to the serious consideration of that august and judicial body.

Dr. Richardson, F.R.S., will take the chair on Friday at a general meeting of the Medical Temperance Association, to be held in the rooms of the Medical Society of London at 4 o'clock, when Dr. Pearce will read a paper on "The Absolute and Differential Diagnosis of Alcoholic Paralysis," and Dr. Norman Kerr one on "The Remarkable Decrease of Alcohol in Workhouses," Medical visitors are invited.

The Local Government Board have instructed Mr. Power, one of their medical officers, to proceed to Ealing, for the purpose of investigating the epidemic of diphtheria which has occurred there. Twenty-eight out of thirty cases are reported to have been supplied with milk from the same dairy, and the milk supply is therefore suspected of having some connection with the outbreak.

The mortality in some of the Continental cities is now very high, exceeding in some cases the birth-rate. In Rome, according to the last weekly official return, the deaths exceeded the births by 10; in Trieste, by 30. Venice shows a still higher percentage, the births reaching only to 68 and the deaths 81. In Breslau and Buda-Pesth the birth and death rates are about equal.

At the Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THE question of "induration" as a diagnostic factor in the discrimination of Hunterian sores came on for discussion at the last meeting of the Royal Medical and Chirurgical Society, when Mr. Holmes, on behalf of Mr. W. E. Cant, of Devonport, communicated a paper which analysed no fewer than 3,300 cases of the disease observed among female patients at the Royal Albert Hospital. The author arrived at the conclusion that women much more frequently than men fail to exhibit the familiar hardness of sore notwithstanding the generally adopted opinion to the contrary. Strong support was given to this view by Dr. C. R. Drysdale, who instanced his experience at a small lock hospital as confirming Mr. Cant's views, but he considered it very probable that induration would be influenced in degree by the situation of the lesion. Mr. Harrison Cripps, too, thought that position was everything in this connection. In commenting on the paper, Mr. T. Holmes remarked on its being a record of facts only, and commended the author for avoiding to enter on speculations such as distinguished the usual labours of syphilographers. His own experience accorded with that of Mr. Cant, and he took the opportunity afforded him by the discussion to deprecate the mischief caused by the repeal of the Contagious Diseases Act.

Mr. R. W. Parker, seemingly struck by the difficulties of diagnosis which acceptance of the views promulgated by previous speakers might occasion, besought to know what, if not induration, could be held to be the test of a chancre; what was its characteristic, and what features of it were to be regarded as resulting from mere irritation, and what from the action of the true syphilitic virus? This series of queries evoked from Dr. Drysdale the information, important though possibly apparent, that absence of induration alone should not be held to prove identity of Hunterian chancres with the soft sores, and in the same association Mr. Cant urged that when present, induration was the best character to depend on in a syphilitic sore. On the whole the debate did not add anything material in this direction, though the information contained in the paper as to the nature and distribution of chancres in women is of the most valuable kind.

A case of actinomycosis hominis formed the subject of the next communication, by Dr. R. Hebb, Dr. Sturges introducing it to the Society. Dr. Sturges' idea relative to the rarity of the disease was combated by Dr. T. D. Acland, who mentioned that he had himself encountered four examples in his personal experience. Among cattle it was very common, and in Europe no fewer than thirty cases had been reported in which it occurred in the lungs of human beings.

MEDICAL SOCIETY OF LONDON.—MONDAY, FEB. 14.

DR. LEOPOLD SERVAIS, of Antwerp, read a long and interesting paper on two really formidable operations which he had performed for the removal of cancerous (?) growths involving the superior maxillary bones. Photographs of the patients prior to operation were handed round, and showed what exceptional dimensions these tumours had attained. Both operations were successfully carried out, and recovery took place very promptly in both cases. We would venture to suggest that when illustrious foreigners favour us with papers, these should be read by one of the secretaries, as nothing is more fatiguing than a long paper in English strongly redolent of their foreign origin.

Mr. Bowreman Jessett showed a woman from whom he had removed a large sarcomatous growth involving both upper maxillæ, and exhibited the specimen, comprising both superior maxillary bones, together with microscopical sections of the tumour. The growth was of a myeloid nature. The patient had made a good and rapid recovery, and was very little inconvenienced by the deprivation of what is generally considered an indispensable portion of *the* upper extremity.

Mr. Morgan, in paying a high compliment to the operators whose papers had just been read, renewed the subject of operations in this region, and quoted cases in his own experience.

The attendance of members was very meagre, owing probably to the oration at the College of Surgeons.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

AN extra meeting of this Society was held in the Faculty Hall on Friday, the 11th inst. Dr. Joseph Coats presided, and there was a large attendance. The public business was announced to be a "Discussion on the Pathology and Treatment of Cerebral Abscess." Dr. William McEwen opened the proceedings by a very lengthy essay on the general aspects of cerebral abscess, which was simply a *résumé* of the subject with some cases interspersed. There was really nothing very controversial in Dr. McEwen's remarks save possibly his contention that cerebral abscess depended on these omnipotent germs of which we hear so much and see so little. Mr. Arthur E. Barker, of London, followed with a paper having no earthly bearing on Dr. McEwen's, but containing some good hints and some valuable information. Dr. Barr followed with a paper, said to be an old one, on disease of the middle ear, and consequently quite irrelevant to the two preceding papers. Much of Dr. Barr's paper was more suited to a popular than a professional audience. It is quite a new use of the term to call the reading of such lengthy and dreary essays a "discussion," and it was felt by many that the performance was a mere waste of time.

Edinburgh.

[FROM OUR OWN CORRESPONDENT.]

SIR DOUGLAS MACLAGAN.—Last week, Sir Douglas Maclagan, Professor of Medical Jurisprudence and Public Health in the University of Edinburgh, was presented with his bust and portrait by his many friends. The immediate occasion of the presentation was the honour recently received at the hands of Her Majesty. The ceremony took place in the Freemasons' Hall before a large and representative company. The Lord Justice General occupied the chair, and was supported by Lord Moncrieff, Lord Balfour of Burleigh, the Lord Provost of Edinburgh, Sir Alexander Christison, Sir W. Muir, &c. Apologies of absence were read from Sir Joseph Fayrer, Sir Noël Paton, Mr. Erichsen, &c. In making the presentation, Lord Inglis made a most happy speech, stating that his chief qualification for the honourable post of presiding lay in the fact that he had been the intimate friend of Sir Douglas, since 1819, when they occupied the same benches at the Royal High School. He referred to the many honours which had fallen to the lot of the veteran professor, instancing, in particular, the curious co-incidence that Sir Douglas Maclagan had followed the example of his father in holding the offices of President both of the Royal College of Surgeons and of the Royal College of Physicians of Edinburgh, Sir Douglas had served the University well for close on twenty-five years, while by his manly, citizen-like bearing, he had always been a pleasant link between the University and the town. He was, moreover, a man of highly cultivated mind, well versed in literature, both classical and modern, a poet, a sweet singer, an ardent sportsman, a loyal volunteer, and a great officer in Her Majesty's body-guard for Scotland. Sir Douglas wore his years so lightly, they could not think of him as an old man. They trusted that he would long be spared to them. In accepting the bust and portrait Sir Douglas Maclagan said that his heart was too full of gratitude to permit of adequate expression. He thanked them all from the bottom of his heart. The bust which pleasantly recals the features of the honoured professor, is the work of Mr. Hutchinson, R.S.A., while the portrait is a charming likeness in Mr. Geo. Reid's best style.

University of Edinburgh.—The late Lord Gifford, one of the Senatus of Justice, Edinburgh, has bequeathed £80,000 to the four Universities of Scotland, for the foundation of chairs of Natural Theology. Edinburgh is to have £25,000 St. Andrews £15,000, and Glasgow and Aberdeen, £20,000 each.

Professor Rutherford's Apology,—Professor Rutherford has written to the *Lancet*, informing the members of the profession that no "gross charges" were brought against his late assistant by him, nor were illegal charges or any kind intentionally made against him, even by imputation! The letter has given rise to much comment in Edinburgh. It is felt more distinctly than before that the University Court must interfere with a view to getting at the bottom of the disturbing scandal.

Edinburgh Medico-Chirurgical Society. — The Edinburgh Medico-Chirurgical Society is to hold a special meeting to-night, for the discussion of empyema, in its medical and surgical aspects. The meeting will take place in the hall of the Royal College of Physicians of Edinburgh, which has been granted for the occasion. We shall give a *résumé* of the debate in our next issue.

Deputation to the Government.—A deputation from the University of Edinburgh had an interview with Mr. Goschen at the Treasury on Monday last, with reference to an application for a Government grant of £12,000 to meet with the cost of a site for the erection of an academic hall for the University of Edinburgh, the private donor having offered to provide the cost of the hall, which will amount to £40,000 or £50,000. The Marquis of Lothian, Sir William Muir, and Sir William Turner spoke in support, and Mr Goschen promised to give the subject his best consideration.

◆

Durham County Hospital.—The annual meeting of the governors and subscribers to this institution was held on the 1st. inst., when it was reported that during the past year there had been 419 in- and 1,513 out-patients, a decrease of 52 in-patients, and an increase of 270 out-patients, as compared with the preceding year. The income for the year was £2,286, and the expenditure amounted to £3,590, the latter amount including a balance of £1,229 brought forward from the year before.

Correspondence.

HOMŒOPATHY AT THE MARGARET STREET INFIRMARY FOR CONSUMPTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I am surprised that no notice has been taken by any of the medical periodicals of the very strange proceedings which have lately been enlivening that most respectable and decorous institution, the Margaret Street Infirmary for Consumption. From its foundation some forty years ago, until quite lately, it has been a recognised stronghold of orthodox medicine. But for several years two of its medical officers having been perverted to the homœopathic creed, have been practising that odious system on the patients of the infirmary. After having suffered the innovation in silence for some time, a majority of the medical staff resolved to purge their institution of the heresy. They could not prevail on the senior physician to join them. He holds that every member of the staff has a perfect right to adopt any remedies and any method of treatment he thinks best, and that the laws of the infirmary give no authority to anyone to interfere with the medical views and practice of any of the medical officers. The majority naturally thought otherwise, so they stirred up the executive committee to put a stop to the innovation. The executive committee therefore addressed a letter to the heretics calling on them to cease their homœopathic treatment or else resign their appointments as physicians to the infirmary. The two members of the staff flatly refused to do as the committee required them. Thereupon the committee called a special general meeting of the governors to consider the matter. But when the special general meeting assembled on the 20th of December last, it was found that some formality required by the laws in the summoning of a special general meeting had not been complied with, therefore the chairman decided that they could not proceed to business; so it was adjourned to a future period not specified,—in fact, *sine die*. The annual general meeting which is fixed to take place on the 4th Wednesday of January of each year, was held as usual this year, and an unusually large number of the governors attended. Lord Grimthorpe was elected chairman. After some formal business, one of the governors moved, that the action of the seven members of the medical staff in issuing a circular to the governors in which they called themselves "The Medical Staff" was irregular. The chairman gave it as his opinion that these gentlemen, though they constituted a majority of the medical staff, had no right to call themselves "The Medical Staff" and the meeting voted that their conduct in so doing *was* irregular." The same governor next moved that the executive committee in calling on the two medical officers to desert from their peculiar practice or to resign, had also committed an irregularity. This motion was also agreed to by a majority of the governors present. The practical result of the annual meeting therefore was that the members of the medical staff could not be interfered with in their practice of any method they chose to adopt, and that they were practically irremovable. Moreover, the adherents of orthodox medicine and the executive committee were, by the votes of the governors, censured for their endeavour to preserve their institution from the contamination of homœopathy. In our medical societies where we are all of one mind, our opposition to homœopathy seems quite right and proper, and we all feel satisfied that we are consulting the honour and dignity of medicine in suppressing the heresy, but some how or other it did not look quite right for the adherents of scientific medicine to be opposing liberty of opinion in medical matters before a miscellaneous assembly, who, of course do not understand the feeling of the profession towards homœopathy, but think that medicine is a sort of "go as you please" race, and that anyone may practice just as he likes, which of course is true in a general way, but cannot be permitted in an institution established for orthodox medicine, like our infirmary. Since the London College of Physicians in its famous resolution of 1881, said it had "no desire to fetter the opinions of its members in reference to any theories they may see fit to adopt in the practice of medicine," the homœopaths may taunt us with attempting to do what our college deliberately repudiates. Of course the defenders of scientific medicine will not sit down patiently under the rebuff administered to them by a set of non-medical persons, but will continue their efforts to remove the slur on the orthodoxy of the infirmary caused by the presence of these two homœopathizing members of the medical staff. But it is difficult to see what course they can adopt in the face of the laws of the infirmary which seem to allow the medical officers to introduce any novelty of practice they may think fit. Lord Grimthorpe, who is an old and constant supporter of the infirmary, strongly deprecated the plan of a special general meeting for the discussion of different modes of practice, which he said would only make a "row," which would be detrimental to the interests of the institution. But something must be done, the burning question is:—What can be done?

I am, Sir, yours, &c.,
A Governor.

London, Feb. 10, 1887.

◆

INTRA-PERITONEAL HÆMATOCELE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In your report of the proceedings of the Pathological Society (*Medical Press*, Feb. 9) occurs this sentence: "Dr. Griffiths urged the belief that, notwithstanding recent controversy, effusions of blood in this region are true intra-peritoneal hæmatoceles, and that the hæmatomata of Mr. Lawson Tait and others are principally a new disease resulting from operative interference with the broad ligament." Of course I do not know whether your reporter or Dr. Griffiths is responsible for the meaning conveyed by this sentence, but whoever it may be due to, no more complete misrepresentation of what I have written on the subject could possibly be made, nor could the facts I have put on record be more completely distorted.

Effusions of blood arising from ruptured tubal pregnancies are intra-peritoneal hæmatoceles, I have seen not one single exception to this statement. I have never used the word hæmatomata at all, but I have shown what was well known before, that all operations affecting the broad ligament, even removing a parovarian cyst, may result in the formation of an extra-peritoneal hæmatocele, that is a hæmorrhage into the cavity of the broad ligament. The only instance of this kind that ever required interference in my practice, was after the removal of a parovarian cyst. But this extra-peritoneal hæmatocele is not a new disease, and arises from a number of other causes besides interference with the broad ligament, in fact even where the broad ligament has been interfered with, the effusion is due immediately to the occurrence of metrostaxis.

I am, yours, &c.,
Lawson Tait.

Birmingham, Feb. 11th.

[The complaint made by Mr. Lawson Tait should be addressed rather to Dr. Griffiths than to ourselves, since the *résumé* of our reporter is justified by the official abstract of the paper (*vide Lancet* and *British Medical Journal*, Feb. 5) published elsewhere. The word "hæmatomata" was employed by Dr. Griffiths as an alternative term for "sub-peritoneal effusions," and it may be fairly questioned whether Mr. Tait has any ground for his complaint, since he is not accused of calling these blood tumours intra-peritoneal.—Ed.]

Literature.

A WEST INDIAN SANITORIUM. (a)

Wonders will they say never cease, and so we are here told, by way, doubtless, of confirming this truism, that, contrary to common surmise or report, Barbados "is (now) the healthiest station at which British troops are quartered." That may be so as we write, or in the estimation of our author, but it is not so in the opinion of sanitarians or physicians, and Mr. Moxly must be well aware that the medical records he appeals to are beyond the reach of experts as well as of the general public. They could only be referred to, if at all, at the War Office, or through a motion to that effect in the House, and Barbados must show that it is the "real and original" Elysium our author says it is, 'ere either of these measures or applications are entertained or enforced.

No doubt its present salubrity would compare favourably with that of the past, but then "the regulation number of men to a barrack-room was at the rate of one for every eighteen inches along each side wall with another row down the middle given equal space; that is, for a room thirty-nine feet long, seventy-eight men who used to live in it night and day" were huddled together, and it only requires a glance at Parkes' Hygiene to ascertain what that means. The condition of West Indian military camps and hospitals was indeed almost, if not quite, on a level with the condition of the jails and infirmaries that were visited by Howard during the first fifty years of the last century, but all this is now changed, and hence, in great part, at least, the present greater healthiness of these stations or quarters. Our author, indeed, admits all this, and thereby appears to us to cut the ground from under his own feet. Anyhow, to invite invalids to Barbados at this stage, with so many better or more attractive ones on all sides of us nearer home seems to us to savour of a blunder—if it is nothing worse—and this is, perhaps, as much as we need here say about the superior salubrity of this island.

As to the other features or attractions of the place, they are neither so varied nor so striking as to call for any extended notice at our hands, and the book says nothing about "Speculation-Spins," or "Garrison-hacks." The local market is probably too limited for ventures of that kind, and the society would appear to be almost entirely military. It is at least pleasant to hear that though the thermometer runs up there at times to 85° or more in the shade, "a death from sunstroke is absolutely unknown in the island." Then, again, scarlet fever is so mild in its seizures here that anxious mothers actually sigh for its supervention in the persons of their children while they are on the spot, so that one might go farther and fare worse than on a trip to Barbados, and to those who contemplate such a trip, or such an outing—for it is little more in these days—we can heartily recommend this candid, outspoken, and, withal, sensible and comprehensive little compilation.

◆

Improvements in Medical and Surgical Appliances.

A NEW DISINFECTING POWDER.

Condy's Fluid is probably as well known and as extensively used as any disinfectant with which the profession and the public are acquainted. Introduced originally by Mr Condy in 1857, it has held its own, and now in order to meet the growing demand for powders, as being more convenient, and less dangerous, Messrs Condy & Mitchell have manufactured a powder which combines the oxidating ingredients of Condy's fluid with a boro-sulphate antiseptic base. The advantages claimed for this new disinfectant, or rather old disinfectant in a new form, are—that it can be used in the dry state direct from the tin for sprinkling over offensive matters or foul surfaces; and being entirely soluble, it can be added to water to form a disinfecting fluid. Solutions of any strength, from faintest pink to complete saturation, are instantly obtainable. Condy's powder, like the fluid, leaves no odour, so that its effects can be ascertained. It cannot act as a mere blind for smells, and thereby inspire a false sense of security. Both the permanganate and boracic acid arrest decomposition, and this is generally accepted as proof of being anti-microbic; but independently of this, each has been shown by experiments to be destructive of bacteria and infusoria, although its constituents are non-poisonous to man. Considering how great a favourite Condy's Fluid has always been with the profession and the public, a great future is undoubtedly open to this powder.

◆

AN UNBREAKABLE THERMOMETER.

The Unbreakable Clinical Thermometer manufactured by Messrs. J. C. Fell & Co. is an ingenious endeavour to lessen the risk of breakage which the use of these fragile articles involves. By means of a very neat arrangement of india-rubber tongues inside the case, the thermometer is held perfectly fixed, and when the top is screwed on, it may fall with impunity. As it is generally while inside the case that they are broken, the danger will evidently be reduced to a minimum. It is about the same size as the ordinary thermometer case.

(a) "A West Indian Sanitorium, and a Guide to Barbados.' By the Rev. J. H. Moxly. London: Sampson Low & Co. 1886.

◆

IMMISCH'S WATCH-FACE CLINICAL THERMOMETER.

An important improvement has been made by Mr. Immisch in his clinical thermometer, which is calculated to make this instrument still more popular. It had been suggested to the maker that the pointer should be capable of being fixed when in use. This difficulty has now been effectually overcome by introducing a stop, which absolutely fixes the pointer when a temperature is taken. By simply pulling out a small knob just outside the pendant the pointer becomes fixed, and remains so till a push in the opposite direction again frees it. In appearance the little instrument is the same, and this addition does not in the least interfere with its reliability.

◆

THE EMERGENCY POCKET HYPODERMIC CASE.

We deferred noticing this little pocket case until we could speak from actual experience of its value. After a fair trial with most satisfactory results we recommend it to the profession. Useful to the city practitioner, it is almost a necessity to the country doctor, who, at a distance from the surgery in a case of emergency, cannot imagine how much trouble and anxiety he will be saved until he finds this miniature dispensary in his pocket, with its neatly arranged tubes of atropine cocaine, digitalin, ergotinin, morphia, pilocarpine, &c., &c., its tiny pestle and mortar for crushing and dissolving the tabloid about to be injected, and little silver syringe. Truly *multum in parvo.*

The makers are Messrs. Burroughs, Welcome, & Co., Snow Hill, London.

◆

NEW PLASTER OF MENTHOL.

The National Plaster Company of 67 Holborn Viaduct, London, have forwarded us a sample of an improved Menthol Plaster. It combines the advantages of the ordinary porous plaster with the peculiar qualities of menthol—qualities which are more marked when it is used in the form of a plaster than in the cone. It will, doubtless, be found very useful in those cases of local rheumatic or neuralgic pain, in the treatment of which menthol has acquired a reputation.

◆

MEDICATED SOAPS.

We have received from the Milton Chemical Company (Glasgow), a selection of their Medicated Toilet Soaps of various shapes, sizes, and descriptions. The Iodoform soap is a novelty, and has the merit of not conferring the not very popular odour of that otherwise useful drug. The Corrosive Sublimate Soap, which may be used in the cases in which it is indicated without fear of any untoward results from absorption or local irritation. The Blue Gum Tree and Yara Yara Soaps are also first-class soaps, with their own powerful but agreeable and characteristic odours which they impart to the skin.

Medical News and Pass Lists.

The Hunterian Oration.—The annual oration in memory of the illustrious Hunter, was delivered on Monday afternoon in the theatre of the Royal College of Surgeons of England, by Mr. Savory, President of the College. The oration will be found in the columns of the *Times* Newspaper of Tuesday.

Bradford Children's Hospital.—At the annual general meeting of subscribers to this institution on the 28th ult., the secretary reported that the receipts amounted during the year to £552, and the expenditure to £526. The fund which was raised for the extension of the hospital amounts to over £4,600, and the committee are in search of a building suitable for the purpose.

A Fortunate Hospital.—In these days of hospital deficiency it is refreshing to learn that the receipts of at least one during the past year have nearly doubled its expenditure. At the fifty-ninth annual meeting of the governors of the Royal Free Hospital held last week, the secretary reported that the receipts from all sources amounted to £40,083, and the total ordinary expenditure to £11,121, as compared with £11,085 in 1885. The number of in-patients admitted was 1,813, the daily average in the wards being 138, as against 135 in 1885. The number of out-patients who received advice and medicine was 22,191.

Anderson's College Medical School.—At the ordinary meeting of the Faculty of Physicians and Surgeons of Glasgow, held on the 7th inst., Dr. John Pirie, Dr. Thomas Lapraik, and Dr. A. L. Kelly were elected Governors of Anderson's College as constituted under its new trust.

University of Cambridge.—At a congregation held on Thursday last, February 10th, the undermentioned degrees were conferred :—

Doctor in Science (Honoris Causa).—Alexander Agassiz, Professor of Comparative Zoology in the University of Harvard, U.S.A.

Bachelor in Medicine.—Edward John Sidebotham, Caius.

Bachelor in Surgery.—Edward Lycett Burd, Caius.

University of London.—The following Candidates having passed the examination for the Preliminary Scientific (M.B.) during the recent meetings of the Examiners, have received the M.B. of this University :—

Entire Examination.—First Division.

Ballance, Hamilton Ashley
Coles, Charles
Davies, Alban Davy
Dow, John Hardman
Fullerton, Alexander Young
Gibson, Henry Wilkes
Harris, William James
Parsons, John Herbert
Powell, T. Morgan Jones
Rider, Alonzo George
Sheen, Alfred William
Smith, George Samuel Stone
Ta'Bois, Alfred Charles
Umney, William Francis
Whitfield, Arthur
Whittaker, C. David, B.A.

Second Division.

Clegg, Richard
Davson, James B. Hoghton
Rows, Richard Gundry
Wilson, John Gratton

Passed Two Subjects of the Examination.†

Arnold, Frank Arthur (C., P.)
Badger, Arthur Roscoe (C., B.)
Bakewell, Robt Turle (C., P.)
Braithwaite, Charles B. (C., P.)
Carter, Ed. Barrett (C., B.)
Colclough, William F. (C., P.)
Daly, Stephen Joseph (C., P.)
Davies, Howard Owen (C., B.)
Given, John Cecil M. (P., B.)
Gowring, Benjamin W. N. (C., B.)
Grant, Francis Octavius (P., B.)
Green, Douglas, Richard (C., P.)
Huntley, Edgar (C., B.)
Mitchell, Stanley H. (C., P.)
Rentzsch, Sigismund H. (C., P.)
Seton, Bruce Gordon (C., P.)
Tribe, Alfred Gladstone (C., P.)
Wilmot, P. McKinnell C. (C., P.)

Passed One Subject of the Examination.†

Biggs, John James E. (C.)
Briscoe, John Edward (P.)
Brown, John James (P.)
Buckley, Joseph Richard (P.)
Davies, William Thomas (B.)
Ede, Frances (P.)
Finley, Harry (B.)
Fisher, John Herbert (C.)
Gilmour, Robert Thomas (P.)
Gully, Robert Cullum (B.)
Gutteridge, Edwin Lewis (P.)
James, Rupert (P.)
Jerome, George Percy (C.)
Johnson, Frederick (P.)
Langworthy, William S. (P.)
Nesfield, Stephen (P.)
Northcote, Percy (B.)
Parker, Henry Thomas (C.)
Penberthy, William (P.)
Reynolds Austin Edward (P.)
Rowbotham, Herbert H. (P.)
Slater, Howard (B.)
Smith, Reginald (B.)
Spencer, Charles B. P. (C.)
Sturge, Caroline (B.)
Tibbetts, Thomas Major (P.)
Tracey, Henry Eugene (P.)
Vincent, Thomas Swale (P.)
Wainwright, William L. (C.)
Wallace, Cuthbert Sidney (C.)
Way, Richard Henry (P.)
Williams, Lewis (B.)
Williamson, John (P.)

† The subjects taken up by these Candidates are indicated by initials after the name.—C. = Chemistry; P. Physics; B. Biology.

Notices to Correspondents, Short Letters, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attenion to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sendingthem to the Editor.

DR. GRAILY HEWITT.—Paper on "Interference with Locomotion as a Uterine Symptom" received; will appear in an early number.

SHIP SURGEONS.

U. S. C.—It is quite impossible to obtain. To attempt to give the desired information would be misleading and useless. We may, however, state that, generally speaking, whenever cabin-passengers are carried, the surgeon messes with them in the saloon, though at other times, as, *e g.* in port, he has to go down lower, and *feed* with the mates. It would be incorrect to apply the term *dine* to such a proceeding. A. S. C. might almost as well inquire where the animals "dine" at the Zoological Gardens. *They dine in their dens;* and these dens are almost without exception lighter, sweeter, and cleaner than an "officers' mess-room" on board ship: the language, too, is often less disgusting. As to uniform, ship surgeons are generally expected to wear some kind of uniform in the way of navy blue, and a certain amount of brass, but the latter need seldom extend lower than the cap.

EXTRA POSTAGE.

DR. BROWNE.—The postmaster who charged you extra postage because the journal was "stitched" does not understand his duties, and should be relieved of his functions. Our publisher has written to the Postmaster-General to this effect. A halfpenny stamp will carry this journal to any address in the United Kingdom, no matter what its weight, and whether stitched or unstitched. No subscriber should allow any out-of-the-way postmaster or postman to charge him extra postage Any attempt should be at once resisted, and complaint sent to the Postmaster-General or to our publisher.

VACCINATION FEES.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I wish to know if a medical officer of a workhouse is or is not entitled to payment for cases of successful vaccination performed on children. An answer will much oblige,

yours truly

N. J. M.

[No. The Act of Parliament provides only for payment of a fee to the dispensary medical officer. Therefore a workhouse medical officer, if he vaccinates, cannot be paid.—ED.]

PLURALITIES.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—In the issue for Feb. 2nd of the *Medical Press and Circular* I observed two paragraphs which seem to require some explanation. In the first paragraph, regarding the appointment of a dispensary doctor to the post of Assistant Medical Officer to the Dublin Metropolitan Police, the gentleman is congratulated on his appointment. In the second paragraph, regarding the appointment of a dispensary doctor to the office of Assistant Physician to the House of Industry Hospitals, the opinion is expressed that pluralities ought not to be allowed. Is there not a discrepancy here?

I am, Sir, yours, &c.,

Dublin. ALEXANDER STEWART.

[There is no discrepancy. The offices of dispensary medical officer and assistant medical officer to the police are quite compatible, and neither need clash with the other. But, we think, and Dublin experience proves, that hospital clinical teaching and dispensary duty can scarcely be well done by the same person, the hours of duty being incompatible. We have not the least desire to discourage any person from holding positions which he can do justice to, but it seems to us that when a practitioner becomes an hospital teacher, he might advantageously leave the dispensary for some one else.—ED.]

◆

Meetings of the Societies.

WEDNESDAY, FEBRUARY 16TH.

SOCIETY OF ARTS.—At 8 p.m., Mr. Henry H. Cunynghame: Uses, Objects, and Methods of Technical Education in Elementary Schools.

THURSDAY, FEBRUARY 17TH.

ROYAL INSTITUTION OF GREAT BRITAIN.—At 8 p.m., Prof. A W. Rücker: Molecular Forces.

PARKES MUSEUM OF HYGIENE.—At 5 p.m., Mr. Charles E. Cassal: Food Adulteration and Analysis.

HARVEIAN SOCIETY OF LONDON.—At 8.30 p.m., Mr. Sedgwick: Notes on the Collapse of Cholera. Dr. Sidney Phillips: Some Points in the Treatment of Fever. Dr. A. H. N. Lewers: The best means of Dilating the Cervix Uteri.

FRIDAY, FEBRUARY 18TH.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—At 7.30 p.m., Mr. C. E. Paget: A Practical Illustration of the Protective Influence of Vaccination.

ROYAL INSTITUTION OF GREAT BRITAIN.—At 9 p.m., Mr. William Crookes: Genesis of Elements.

MEDICAL TEMPERANCE ASSOCIATION.—At 4 p.m., Dr. W. Pearce on "The Absolute and Differental Diagnosis of Alcoholic Paralysis." Dr. Norman Kerr on "The Remarkable Decrease of Alcohol in Workhouses."

ACADEMY OF MEDICINE IN IRELAND.—The Surgical Section will meet in the College of Surgeons at 8 o'clock. Papers: Mr. J. K. Barton: On Œsophagotomy for the Removal of Foreign Bodies. Mr. McArdle: Resection of the Pylorhs. Mr. J. H. Scott: On Nerve Suture.

Vacancies.

Doncaster General Infirmary and Dispensary.—House Surgeon, Salary, £100 per annum, with board and residence in the house. Applications, with testimonials, to be sent to the Hon. Secretary not later than Feb. 21st.

Royal Albert Hospital, Devonport.—Honorary Surgical Staff. Applications, with testimonials, should be sent addressed to Chairman of the Selective Committee not later than Friday, the 18th of February.

West Herts Infirmary, Hemel Hempstead.—House-Surgeon and Dispenser, who shall also be Assistant Secretary. Salary £100 per annum, with board, furnished rooms, fire, lights, and attendance. Any further information can be obtained from the Assistant Secretary.

The General Hospital, Birmingham.—Two Assistant House-Surgeons. There are no salaries attached to the posts, but residence, board, and washing will be provided. Applications, with copy of testimonials, addressed to the House-Governor, to be sent in on or before Saturday, February 26th.

Preston and County of Lancaster Royal Infirmary.—Senior House Surgeon. Salary at the rate of £100 per annum, with lodging, washing, and board, exclusive of wine, spirits, and malt liquors. Applications, with testimonials, must be sent free on or before the 28th inst., addressed to the Secretary, Fishergate, Preston.

Appointments

BRODIE, F. C., M.R.C.S., L.R.C.P., L.S.A., House-Physician to the Middlesex Hospital.

CARTER, T. E., M.B.Lond., M.R.C.S., Surgeon to the Stamford and Rutland Infirmary.

CHAMPNEYS, F. H., M.A., M.B.Oxon., F.R.C.P.Lond., Consulting Physician to the Lying-in Hospital, Lambeth.

COSGRAVE, E. MACD., M.D., M.K.Q.C.P.I., Physician to the Heytesbury Industrial School, Dublin.

JORDAN, F., F.R.C.S.E., Consulting Surgeon to the Queen's Hospital, Birmingham.

POLLARD, R., M B.Dur., M.R.C.S., Physician to the Western Hospital, Torquay.

RAMSAY, R. H., M.D., C.M.Glas., Physician to the Western Hospital, Torquay.

SHORT, T. S., M.B., M.R.C.S., L.S.A. Cert San. Sci. Camb., Resident Medical Officer to the Jaffray Hospital, Birmingham.

STEWART, J., L.F.P. & S.Glas., Poor-law Medical Officer and Public Vaccinator for the District of Rotherham.

WHARRY, H. G. O., M.R.C.S., L.S.A., House-Surgeon and Secretary to the Scarborough Hospital and Dispensary.

Births.

BUSH.—On Feb. 10th, at Beaufort Lodge, Hounslow, the wife of Surgeon-Major Cecil Bush, M.B., Medical Staff, of a son.

CHEESEWRIGHT.—On Feb 11th, at Rawmarsh, Yorks, the wife of J. F. Cheesewright, M.R.C.S., of a son.

HEUTSCH.—On Feb. 11th, at 4 Portland Place, Camberwell, the wife of J. Page Heutsch, M.R.C.S., of a daughter.

RIEU.—On Feb. 10th, at 28 Woburn Square, London, the wife of Chas. Rieu, of a son.

Marriages.

COLTHURST—DAVIS.—Feb. 7th, at Holy Trinity, Paddington, Ludlow Tonson Colthurst, M.D., Surgeon R.N., to Lilie, eldest daughter of John Davis, Esq., B.L., of Youghal, co. Cork.

GOSTLING—PARKINSON.—On Feb. 10th, at St. Mark's Church, Hackney, W. Ayton Gostling, M.D., of Worthing, to Francis Marion, only daughter of Mr. G. H Parkinson, of London.

Deaths.

AMBLER.—On Feb. 6th, at 14 Colville Square, Bayswater, W., suddenly, Vincent Ambler, M.D.

FOOTE.—On Feb. 3rd, at Croft's House, Rotherham, Yorks, Harry D'Oyley Foote, M.D., M.R.C.S.E., L M., aged 52.

GASKOIN.—On Feb. 5th, at Caerleon, Monmouthshire, George Gaskoin, M R.C.S., late of Westbourne Park, London, aged 70.

HOWARD.—On Feb. 6th, at New Buckenham, Norfork (of diphtheria), Herbert Howard, M.R.C.S., L.R.C.P.Lond., aged 25.

MATHESON.—On Feb. 5th, at his residence, Granville Place, Portman Square, London, Duncan Matheson, L.R.C.P.Ed., L.F.P.S.Glas.

SMITH.—On Jan. 27th, at Portland House, Cheltenham, Thomas Smith M.D., M.R.C.P.L., aged 74.

Original Communications.

ON THE MANAGEMENT AND SELF-MANAGEMENT OF GOUT, OR THE URIC ACID DIATHESIS, AND "THE GOUTY."

By J. MORTIMER GRANVILLE, M.D.

THE remarks I have to make about gout are briefly these First, it is on the increase, and is now affecting classes of the population which were in former times free from its ravages. Second, its type has so changed that it is no longer instantly recognisable as it used to be. Third, it is bringing forth a crop of affections which are most grievous in themselves, hurtful to the individuals in whose organism they appear, and detrimental to the estate of health and happiness of which we are only the tenants for life, and for which as trustees, we are accountable. Fourth, this extension of the evil, this misleading change in its type, this development of new forms, and entail of further bad consequences, are in large measure, if not mainly, due to the views we have, in recent years, been led to take of the nature of the so-called "disease" and the manner of its causation. No one will fail to perceive that these are allegations of considerable gravity, and it is in the fullest sense of responsibility, I venture to make them.

In so far as gout is the result of an abnormal habit, or disorderly performance, of certain of the organic functions, due to an inherited defect, or habit, or both, it follows that this malady, like other constitutional peculiarities, whether good or evil, must have a tendency to increase with the population. And the rate of its increase will be greater or less than the rate of increase of the population in proportion as the entail of disease or disorder descends chiefly from the male or the female element of the community. Now it is noteworthy that whereas so recently as the commencement of the present century gout, in its divers forms, principally appeared among men, it is now decidedly prevalent among women. This is precisely what we should expect from the known laws of heredity. The fathers of the women now in their maturity were gouty, and their daughters are exhibiting the characteristics of the "constitution" they have inherited. Atavism, or the missing of one or two generations so far as overt disease is concerned, explains how it happened that the fathers of many gouty women did not actually exhibit the phenomena of gout in their own persons, though in a considerable proportion of instances some one member of the generation "skipped" was decidedly gouty, as though to show that the hereditary malady was present in the family, and entailed, though it did not declare itself in the life-history of the other members. In some families there occurs in every generation one individual who is, as it were, the scapegoat of the rest, and who suffers in his or her own person, as if vicariously, the miseries entailed upon all. This curious and unenviable anomaly is probably more common when the males preponderate in a generation, though there are many conspicuous instances of families in which the victim is wont to be a female. Generally speaking, however, if the males of a family are otherwise fairly healthy, they do not develope gout—even in a family which has the gouty constitution strongly marked and entailed—if the female members are generally affected. There are, however, two forms of gout, one which by preference shows itself in disorders and diseases of the nervous system, and another that puts on characteristic appearances and is more generally recognised. The former as a rule passes from mother to son, and father to daughter, while the latter passes down in direct line from father to son. Atavism is more common in respect to the characteristic gout of the direct line than to the anomalous or masked gout of the oblique descent, though this phenomenon is of frequent occurrence in the history of both varieties.

The "gouty constitution" may be said to mean an inherited tendency to the error of function which produces what we call "the gout," and this inherited tendency increases at a greater rate than the population, because while not all the members of a generation become parents, of those who do, an increasing number are affected with gout. It is not, of course, meant by this observation to imply that a majority of parents in the population are gouty, but the rate of extension or distribution of gout by heredity is proportionally greater than the birth-rate in its totality. We are not dealing with a disease which may or may not spread according to conditions and circumstances, but with an organic peculiarity, a characteristic type of development which obeys the natural laws of the development of species, and which can only be arrested or limited by the determining influences of an altered environment. In short, gout is not at root, so to say, a *disease*, but an aberration of function due to organised habits of life which have during a long series of generations influenced and are still influencing development. The proof that "gout" is increasing cannot be made by an appeal to vital statistics, because unhappily our registration system regards only the maladies that constitute the overt "causes of death," and does not at present, if it ever can, deal with the actual or underworking factors of disease. For example, a *bronchitis* may be accidental or gouty. As a matter of fact, a very large proportion of cases of "senile bronchitis" are probably of this character, although they are not so recorded. We have practically no registration of *disease*, and for the purposes of the Registrar-General's office medical practitioners state only the surface facts, without going deeply into the clinical history of their cases. It would be unreasonable to expect them to do more than they do. Meanwhile, the experience of every competent observer will attest the fact that there are at this moment more cases of gout, or of "gouty" trouble, than have been observed at any previous time within the recollection of those whose memories carry them back for a considerable period. And it is not less notorious that this malady in one or other of its cognisable forms is to be found far more commonly than used to be the case among the patients of hospitals who naturally belong to the lower, or lower middle, classes of the community. Some thirty years ago I remember a physician who was anxious to study this disease in a fairly large number of cases, with a view to the prosecution of a special series of chemical researches, being in such great difficulty to find opportunities for his inquiries that, although attached to a large hospital well placed in a populous district, he intimated his willingness to pay handsomely for every case that could be found for him. Of what was then called rheumatism there was an abundance, but of "gout" proper or even of "rheumatic gout" examples were comparatively infrequent. There could be no such difficulty now, even though the inquirer should fail to recognise the malady under certain of its altered guises and in many of its new developments.

The prevailing types of gout, as we see it, are less conspicuously local, or localised, than the forms of the malady familiar even three or four decades ago. The victim of gout in the generation of our fathers and grandfathers was a man, seldom a woman, with an enormously swollen foot or feet, an agony of acute pain, at least, during the paroxysm, and all the phenomena of an "inflamed" body, and turbulently excited mind. The typical sufferer of to-day, is very nearly, if not quite, as often a woman as a man, the hands are scarcely less commonly affected than the feet, and the pain and swelling are neither as formidable as they used to be. There is a tendency to deposit and consolidation around particular joints rather than enlargement of the whole of the extremity, and although the pain may be severe it is easily relieved, not because our drugs are more potent, but because the stress of the local disturbance is not commonly so great as in former times, and depression and weakness are to be feared and guarded against rather than excitement and strong inflammatory fever. I do not think any one who saw much of gout then, and who sees it now will question the accuracy of these assertions. Of the two maladies, whatever may be their relations or differences, rheumatism is more *acute* than gout as they appear to-day. It is confessedly true that in all disease there has been a modification of type, and sthenic characteristics are now less common than asthenic. Some attribute this change to the gradual disuse of alcoholic drinks, and others, without attempting to explain the fact, cite it as accounting for the change of practice with regard to blood-letting. If physicians ordered bleeding as freely as they prescribed it when we were children, no inconsiderable part of the sick population would succumb to the lancet. Nevertheless, the change of type in gout is especially remarkable, and it is still in progress. The strong belief, I am chiefly concerned, to express is that to this change is probably due the fact that a very notable proportion of cases of gout are not recognised. They do not present the characteristic symptoms of the malady. The stress of the disease does not fall on those parts of the organism in which we have been accustomed to look for and find it; and the unfamiliar forms of disturbance which spring from, and in truth are "the gout," in an undistinguishable garb, and a new and unsuspected guise, may perhaps be disregarded or misunderstood.

Without discussing the underlying *cause* of the gout, whether it be something wrong in the liver or the kidney or the nervous system, we may assume as a fundamental proposition that the problem to solve is how to get rid of an excess of uric acid in the blood. From some cause —no one knows what—the late Sir Henry Holland quoted Aretæus about the gout: Αιτιην δε ατρεκεα μουνοι θεοι ἔοικυῖχν δε ανθρωποι—there has come to exist in the organic life and function of the gouty a tendency to the presence of an excess of uric acid, or sodium urate, in the blood. We do not know *primâ facie* in any particular case, and we cannot always determine, by the most precise methods of clinico-chemical research, whether this excess be due to excessive or too rapid production or to small or too slow elimination. Still less do we know how far this particular element of the gouty state is to be regarded as the cause or as a symptom of the malady of which it undoubtedly forms a prominent part. Now to say the least it is presumption to assume without any certain premises that there is over-production of uric acid through excess of nitrogenous food, and madness to base our treatment on a mere hypothesis, because, if it should happen to be false, we may be depriving the sick and weakly organism of its necessary supplies in our clumsy attempt to prevent excessive production, whereas the whole fault is perhaps non-elimination. Acting on the hasty assumption I am trying to expose, meat has been denied to gouty patients in face of the fact that those animals which feed exclusively on flesh produce very little uric acid, while those which live exclusively on vegetables produce little else than uric acid; and sugar has been condemned, whereas it is demonstrable by direct experiment that sugar favours and augments the elimination of uric acid. To such blunders are those led who begin at the wrong end or jump to conclusions. Knowing no more than we do of the cause or nature of gout, and being simply aware that it is wholly wrong to have so much uric acid in the blood as is found there in gout, the common-sense view of remedial policy must be *to get rid of it*. This is the sole legitimate aim of the physician in dealing with gout, and the more directly and simply he sets himself to accomplish this issue the better it will be for his patient.

How to get rid of the uric acid? That is the question. I do not for one moment suppose, or mean to imply, that the accumulation of uric acid in the blood is the whole cause or essence of "gout," but it is beyond doubt an important feature of the disorder, and that one which, being changed, the morbid state will be changed also. Now uric acid is in a very high and obstinate degree insoluble, and as it cannot pass through the kidney in a crystalline form, it must be carried out in solution. To this end not less than seven or eight thousand times its bulk of water is required, and it is practically necessary that the water holding the uric acid in solution should not be already saturated with, or preoccupied in holding in solution, other acids or salts. Roughly and approximately, seven or eight pints of urine must be excreted daily to get rid of the uric acid formed, and to prevent accumulation. In short, if a gouty man would be well he must drink freely, and while he drinks, take such precautions as will serve to direct the flow of fluid out of the body into the channel which is peculiarly that best suited for the elimination of uric acid, *i e.*, the kidney. It cannot be doubted that in exceptional cases this acid, in combination with one of its corresponding bases, may be got rid of through the skin. Instances are recorded, and some may be remembered, in which the determination to the surface generally has been such as to cause the skin to be covered with a flour-like powder, which might be brushed off. Everybody is familiar with the so-called "chalk stones," which often lie close under the skin, *e.g.*, on the tips of the ears in this malady; and large accumulations of semi-fluid chalky matter in swellings on the extremities and near the joints are common enough. Nevertheless, it is not in this way that the elimination of urates should be sought, and, therefore, it is a mistake to try to promote perspiration in gout; still more is it a blunder to try to get rid of the morbid products by the intestines. The natural, and proper, mode of exit is by the renal excretion, and the gouty patient should keep his skin moderately, but only moderately, warm, and avoid a too free use of aperients, while he drinks copiously and notes that the fluid he imbibes is fully excreted. Both as a matter of observation and as a scientific inference I would strongly press this primary proposition; uric acid must be eliminated by or through the kidney, and to accomplish this the total quantity of renal excretion in every twenty-four hours must be sufficient. If due attention be paid to this matter I am persuaded a very great deal will be accomplished towards the maintenance of health. Another reason for making the renal organ the emunctory is to be found in the opinion which many good investigators have formed that in point of fact uric acid is chiefly produced by the kidney cells, and that when it is found in the blood that is because it has been thrown back into the blood by some block in the kidneys. If this be true, I do not assert that it is, for there is as much or more to be urged in support of the hypothesis that uric acid is formed in and by the liver, this is obviously an additional reason for keeping the renal organs well flushed. In any case the plan of ridding the blood of the uric acid which is in excess, whether that excess be due to over-production or to deficient elimination, by drinking freely and determining the flow towards the kidney is, I am convinced, the common sense and only true policy. If it be objected that the function of the kidney is likely to be impaired by disease in most advanced and not a few early cases of the uric acid diathesis, that is no sufficient objection to urge against the method, because if the blood-pressure be raised in the vessels of the kidney, the tubes are more likely to be filled, and thus kept patent than if they are not thus distended, and as a matter of fact the best treatment for a decidedly gouty or granular kidney is now recognised to be that which mechanically compels its action by favouring the retaxation of its blood-vessels, for example, the exhibition of nitro-glycerine. Moreover, the dilution of the blood itself by an abundant supply of fluid has the effect of rendering it better able to hold the uric acid in solution, and many have thought, and some are still of opinion that an "attack" of gout is, or may be, brought on by the blocking up of the tubes in the kidneys with crystals of uric acid. In as far as this is the fact "flushing" is the obvious remedy.

Assuming then that the gouty should make it a point of policy to drink very freely, what is it best they should drink? There is no other such solvent of uric acid or urate of sodium as pure water. I have very little hesitation in asserting that the gout may be kept in abeyance if not cured by any one who will make it a practice to drink some three or four pints of water daily. Cullen says, "for preventing or moderating the regular gout, water is the only proper drink." I would not, however, go so far as that for I believe beverages of a moderately stimulating nature are not only desirable but necessary in the great majority of gouty cases. There cannot, however, be any doubt that large quantities of pure or unloaded water ought to be taken with a view to the elimination of the uric acid. I have never been able to understand clearly why so many practitioners insist on their patients drinking water already charged with alkaline carbonates. The task of supplying a base for the acid is a needless one. The blood is already too heavily loaded with salts of uric acid, and is fast depositing the same. The idea of neutralising the acids on which the acidity of the urine depends, is I am persuaded, a misapprehension, for the urine becomes increasingly acid as it passes away the acids of the blood and restores the normal alkalinity of the circulating fluid.

(To be continued.)

◆

ON THE NORMAL SHAPE AND POSITION OF THE UTERUS.

(A Clinical Lecture Delivered at the London Hospital.)

By **G. ERNEST HERMAN, M.B. Lond., F.R.C.P.,**
Obstetric Physician to the London Hospital, &c.

In the production of pelvic symptoms of the slighter kind, much is commonly attributed to displacements and distortions of the uterus. Before we can give their proper significance to these changes, we must understand what is the normal position and shape of the uterus, and to what extent this position and shape are liable to variation in a state of health.

There are two meanings which may be given to the term "normal," when applied to the position and shape of the uterus. 1. It is often taken to mean the position and shape *usually* found on examination of those who suffer from symptoms referred to the pelvic organs. Now these ailments are commoner in women who have had children than in those who have not. Moreover, in women who have had children, examination of the pelvic organs is undertaken and submitted to for slighter reasons than in the case of virgins. Therefore it is the case, that the few healthy women whom a gynæcologist examines, will be mostly women who have been mothers, and the idea of the shape and position of the healthy uterus which he would form from ordinary clinical experience, will represent the usual shape and position of the healthy uterus in parous women.

This shape and position is that the organ is either straight, or with a slight anterior concavity, so that the anterior surface presents an obtuse angle, opening forward; and that the long axis of the uterus lies in, or nearly in, the axis of the pelvic brim, so that no part of the body of the uterus, neither its anterior nor its posterior surface, can be reached by the finger in the vagina. This is the *usual position and shape of the uterus in healthy women who have borne children,* and it is commonly spoken of as the "normal position" and shape of the uterus. In the ordinary nomenclature, deviations from this position are spoken of as "displacements." When the uterus is so far inclined forwards that its anterior surface can be explored by the vaginal finger, this is *anteversion.* When it is inclined backwards, so that the vaginal finger can reach its posterior surface, we have *retroversion.* When the uterus is bent so as to be concave in front, *anteflexion* is said to be present, and when bent so that it is concave behind, there is *retroflexion.*

2. The other meaning which may be given to the term "normal," is the position and shape which is consistent with health. This is the more proper definition. Each one of the deviations from the usual position, anteflexion, anteversion, retroflexion, retroversion, has been shown to be consistent with health, and each has been by some writers considered as *the* normal one. Thus, for instance, Claudius (*a*) of Marburg, maintained in a closely reasoned paper that "the uterus is only in its normal position when it touches the posterior wall of the pelvis." In 70 out of 78 female dead bodies examined by him, the uterus occupied this position.

In comparing the different opinions that have been held as to the natural position of the uterus, we first ask, how has this position been ascertained? There are two ways in which the solution of the problem has been sought, viz., by the examination of the living, and by the dissection of the dead. By making sections of the frozen dead body, we seem to get the best picture of the mutual relations of parts, because we thus see them undisturbed. But this method has the drawback, that great changes occur in the interval between death and the freezing process. Thus in the well known section made by Braune (*b*) and in many of Pirogoff's sections, (*c*) the pelvic floor projection, which in life, according to the largest estimates, is only about an inch and a half, reaches about four inches. The position of the uterus may not be much altered, but the occurrence of such changes is enough to show that the evidence of frozen sections, when opposed to that of examination during life, is not absolutely conclusive. By examination during life we can ascertain the position and shape of the uterus very exactly. We can feel its whole outline by bimanual examination, and if we alter its position it is easy enough to perceive the change produced. Considering also how much more numerous are the opportunities for ascertaining the position of the uterus in the living subject, than those of looking at frozen sections, I regard the results of examination during life as the most trustworthy means of determining the normal position of the uterus. And even if it be the case (as has been sometimes said) that the results of examination of the living are fallacious, that the uterus

---

(*a*) *Med. Times & Gazette.* 1865. Vol. I, p. 5.
(*b*) Topographisch-Anatomischen Atlas, Pl. II.
(*c*) Anatomia Topograpica, Fasc, 3 a.

may be put into an abnormal position by the method of examination; we should remember that the same error must lead to the production of similar pseudo-displacements in the ailing, and in them possibly to unnecessary mechanical treatment in consequence.

The true description of the "normal position" of the uterus is that this organ is movable within certain limits, and any position within these limits is a normal one. The usual position is in the axis of the pelvic inlet, but the uterine body may be inclined in front of or behind that axis, that is, anteverted or retroverted, consistently with health. Neither retroversion nor anteversion is a morbid state, and something more than the mere presence of these so-called "displacements" is required to warrant us in treating them as morbid. The uterus can be pushed up, or pulled down, or pushed to either side; it can also be turned forwards or backwards, or bent forwards or backwards, by appropriate manipulations, without difficulty, and without producing suffering. The limits of these movements cannot be exactly defined, because they are different in different subjects, according to the conformation and firmness of the structures to which the uterus is attached.

Any other definition of the normal position and shape of the uterus than that here given, viz., the position which is consistent with health, comfort, and painless functional activity, is an arbitrary standard, for the setting up of which there is no good reason, and which leads to mischievous errors in practice; such as, for instance, the overlooking of the true causes of symptoms by referring them to what is supposed to be a uterine displacement, but which is really the normal state of things; or the adoption of active treatment, not always free from danger to life, for the removal of conditions which are perfectly healthy.

The same causes that have led to difference of opinion as to the normal position of the uterus have produced also different views about its shape. Taking the class of healthy women whom we more commonly have occasion to examine, the organ is generally either straight as to its long axis, or with a slight curve concave anteriorly. But this, the *usual* shape, is not the only one consistent with health. The form of the uterus is often altered by childbearing. In virgins the uterus may be straight, or it may be, and in the majority is, bent forward. This bend may vary indefinitely in amount. All intermediate degrees are met with, between a uterus which is quite straight, and one so bent that the anterior surfaces of the body and cervix are nearly parallel, and form an acute angle at their junction. Any one of these shapes is normal, that is, consistent with perfect health, and painless functional activity.

The effect of child-bearing is to make the uterus straighter. In parous women, acute anteflexions are less often met with than in nulliparæ. I have found a uterus which was anteflexed before child-bearing gradually become more and more straight after each successive pregnancy. From this effect of functional activity one might expect that the growth of the organ at puberty, or the stimulus of marriage, might have the effect of rendering anteflexion less; but I know of no observations bearing on the point.

The uterus in different patients, possesses different degrees of flexibility. Its tissue may be firm and hard, so that the organ keeps its bent shape during any movement which is imparted to it, and the cervix may be pushed backwards or forwards without altering the shape of the uterus. In these cases the organ, if flexed, can be straightened by passing the sound, but resumes its shape when the instrument is removed, or by pulling down the cervix the bend can be rendered less acute, returning when the cervix is released. When the uterus is taken out of the body after death, the curve is still present. Specimens of uteri of this kind are to be found in several museums. There are other cases in which the uterus is soft, and can be readily bent this way or that. In these cases anteflexion can be made more or less acute by pushing the cervix forward or backward, or even anteflexion and retroflexion can be made to alternate with one another. Such a uterus when taken out of the body, shows no bend, nor any sign of disease. Bandl (*a*) who has investigated by post-mortem examination the shape of the uterus, states his result as follows:—"We find anteflexion still persisting after the uterus has been removed from the body only very seldom, as compared with its frequency in the living. Out of the last 200 cases examined, I only found a plainly persistent anteflexion four times." (This is not due to any very exclusive definition of an anteflexion on his part, as will appear from another quotation in which he says: "In the living woman, the phenomenon of anteflexion and anteversion of the uterus is one so common, that one might without gross error say that all women in whom the uterus is not in a condition of retroversion or retroflexion, present anteversion or anteflexion more or less pronounced.") (*b*)

Softness of the uterus has been looked upon as an effect of malnutrition. (*c*) It may be so, but our knowledge of the causes, significance, or effects of softness of the uterus is purely conjectural. There is no proof that softness of the uterus is inconsistent with a healthy state of the organ, or that great firmness of the uterus is a sign of health. I have found the uterus soft in persons who did not show any evidence of debility, and hard in patients the subjects of wasting disease. I imagine there may be the same differences between different uteri, as to consistence, that we find in the voluntary muscles of different individuals. I do not at all call in question the correctness of Dr. Hewitt's observations that in a certain class of patients treated by him the uterus was soft. But accepting this as a fact, I do not infer from it that in others not suffering from similar ailments the uterus was not soft. And while Hewitt looks on *softness* of the uterus as the condition which produces bending, Schultze (*d*) argues that *hardness* of the uterus, the result of chronic metritis is the cause of changes in its shape and position. The truth is that we have no means of estimating with any precision the state of the uterus as to hardness or softness, and no proof that variations either one way or the other are in themselves evidence of disease.

We have next to ask, how is the uterus maintained in its normal position? Or rather, how is its mobility restricted within normal limits? What are the forces which, under normal conditions, cause it to change its position? and what are those which restore it to its former place when a disturbing force is removed.

The agencies by which the uterus is kept in place are, the pelvic floor, the uterine ligaments so-called, and the intra-abdominal pressure.

In the production of the symptoms which accompany the minor uterine displacements, probably also in the production of the displacements themselves, and certainly in accounting for the variations in those symptoms, the intra-abdominal pressure plays a very important part.

The term "intra-abdominal pressure" means the pressure within the abdomen to which its contents, including the uterus and walls, are continually subject.

The abdominal viscera are affected like all other matter on this planet, by the force of gravity. If not supported, they would fall downwards, that is, in the erect posture, upon the pelvic floor, and in recumbency, upon the dorsal wall of the abdomen. When the structures which should give them support, are so altered that they do not fulfil their duty in this respect, the more weighty viscera, and those exposed to pressure from above do fall downwards, as we see in prolapsus uteri, movable kidney, movable liver, scrotal hernia, &c., conditions which all have in common this feature, that

(*d*) *Lage Veranderungen der Gebärmutter*, s. 67.

they are present when the patient is erect, and disappear, or can be easily altered when the patient is recumbent.

The viscera within the abdomen are also subject to the pressure of the atmosphere, 15lb. to the square inch, which acts on every part of the outside of the abdominal cavity, and if not counteracted by pressure within, would tend to force together the walls of that cavity, to push the diaphragm downwards, the pelvic floor upwards, and the abdominal walls backward. The peritoneal sac in health, is rather a potential than an actual cavity. The viscera which the peritoneum covers are all in close contact with one another and with the walls of the abdomen, and there are only very small interstices left between them, which are filled with a little serous fluid. This can be seen to be the case by looking at any frozen section through the abdomen, in which it will be noticed at once that the outline of the intestine is not round, as it is when removed from the body, but polygonal, from the mutual pressure of the coils. From the way in which during health, the abdominal viscera are closely applied to one another, it results that they give one another mutual support. The pressure of the atmosphere outside, tends to press them together. If we assume that the abdominal walls are rigid above, in front, behind, and at the sides, it is plain that in the absence of any counter-pressure, the atmospheric pressure, 15lb. on the square inch, would tend to press the viscera up, and so counteract the effect of gravity.

But the walls of the abdomen are not rigid. The diaphragm is a muscular arch, which ascends and descends in respiration. The posterior abdominal wall is osseous and muscular, and becomes concave or convex in different postures. The anterior and lateral walls are muscular, and these muscles are sometimes loose and flabby, sometimes firm and contracted. The pressure within the abdomen is continually being modified by the condition of its muscular walls.

The intra-abdominal pressure is the resultant of these three forces: gravity, atmospheric pressure, and muscular action. These forces are always in action, and we cannot separate the effect of one from the other. The amount of this pressure has been measured, and it has been found, by the independent researches of different observers, that, in the same condition as to posture and muscular effort, it varies very little in different persons or in the same person at different times. Thus in the standing posture, without more effort than is needed to keep erect, the pressure within the bowel, or within the bladder, is equal to a column of water from 10 to 12 inches high. During muscular effort it is greatly increased, and in recumbency it is diminished, and may even become less than the pressure externally. We see this sometimes in passing a catheter with the patient lying down, when instead of urine coming out, air is sucked in, and then, on increasing the pressure with the hand on the hypogastrium, urine mixed with many air bubbles is forced out.

The intra-abdominal pressure falls on the pelvic floor vertically downwards, and when it is increased it pushes the pelvic floor downwards. When there are weak spots in the abdominal wall, as in the condition of the abdominal rings which leads to the common kinds of hernia, the intra-abdominal pressure leads to protrusion of the abdominal contents, and if the pelvic floor be weak, yielding and protrusion will take placein that situation.

The essential support of the uterus is the pelvic, or rather, as it might better be called, the abdominal floor. This structure has been described, from a mechanical point of view, in the most luminous manner by Dr. D. B. Hart. (*a*) He points out that it may be regarded as a kind of diaphragm formed mainly by muscular and fibrous tissues, and closing in the abdominal cavity below. This diaphragm is perforated by three openings; the anterior, the urethra, so small as to be insignificant; the posterior, the anus, firmly closed by a strong sphincter, and therefore, except for a few seconds now and then, non-existent. The middle opening, the vagina, is a large transverse slit, and the uterus is implanted into the upper part of the pelvic floor, at the upper part of the slit. This slit forms a valvular opening, closed above by the uterus, in the abdominal floor. It divides the floor into two parts, the anterior part being the upper and more movable, and, in the ordinary condition of the parts, closely applied to the posterior. In labour, the canal for the exit of the fœtus is formed by the anterior segment being pulled up, and the posterior driven down. In the ordinary form of prolapse, the anterior slides down upon the posterior.

This diaphragm, the abdominal floor, is strong enough to bear continually the intra-abdominal pressure, and to resist also the temporary increase in that pressure which accompanies muscular effort. During respiration, the abdominal floor, like the thoracic diaphragm, but to a less extent, ascends and descends; and it is forced downwards also by the increased intra-abdominal pressure which accompanies effort. In these movements the uterus moves with it. When the increased pressure is removed, the pelvic floor rises again, and the uterus with it. Healthy women often follow laborious occupations, and make great and prolonged physical exertions, without suffering.

The most important parts of the pelvic diaphragm, are the pelvic fascia and the levator ani muscle. Below these structures its bulk is made up of skin, superficial fascia, fat, and certain small muscles. The pelvic fascia forms a fibrous partition which completely separates the pelvic cavity above from the perineal space below. The levator ani is a broad fleshy layer which extends from the anterior and lateral parts of the pelvic wall downwards and inwards to the middle line, and forms, together with its fellow of the opposite side, a muscular floor to the greater part of the pelvic cavity. The upper half of the muscle is tendinous, and the lower half muscular. Its fibres pass downwards and backwards, its posterior edge crossing the rectum about an inch and a-half or two inches, above the anus, to be inserted into the coccyx side of the rectum, perineal raphé, and vagina. When the levator ani contracts, the coccyx is drawn forwards, the perineum pulled up, and the sides of the rectum and vagina pressed towards the middle line. With the finger in the rectum or vagina the muscle on each side can be felt as a tense band when the patient is told to draw up.

I arrive at the belief that these structures, the pelvic fascia and the levator ani, are the essential supports of the uterus, by a process of exclusion. The so-called uterine ligaments are in health never tense, so that they cannot act as ordinary uterine supports. The perineum may be destroyed, and the vaginal orifice dilated, without producing prolapse; and repair of these parts, when they are destroyed, and prolapse exists, does not cure prolapse. The only other structures which we can look upon as uterine supports are the fibrous and muscular constituents of the pelvic floor, of which the parts I have named are the most important.

The pelvic floor supports the downward pressure of the abdominal viscera, and prevents descent of the uterus. Bending or turning of the uterus forward or backwards is prevented by the support of the viscera in front and behind it. The pelvic brim is inclined at an angle of about 55 degrees to the horizon, and therefore, if the uterus be in the so-called normal position, that is, the axis of the pelvic brim, it will be inclined at an angle of about 35 degrees. In this position the downward intra-abdominal pressure will fall on the posterior surface of the uterus, and if there be nothing to prevent change in the position of the uterus, this pressure will force it into a position of anteversion. This it may do, but as a rule does not do so, for the viscera in the pelvis,

---

(*a*) Hart & Barbour, Manual of Gynæcology, chap. iii, and other references given there.

as well as in other parts are so packed that they are in mutual contact and give one another mutual support. In front the uterus is supported, below by the bladder, and above, where the bladder ceases to be in contact with it, by small intestine. The bladder is the chief support of the uterus in front. It has been shown, by the experiments of Dr. John Williams (*a*) and those of Drs. Hicks and Goodhart (*b*) and can be observed clinically, that when the bladder is very full, the uterus is by it carried upwards and backwards. (*c*) In ordinary circumstances this viscus is regularly alternately gradually filled and suddenly emptied. It is emptied, partly by its own contraction but partly also by the intra-abdominal pressure. This is exerted by the pressure of the superincumbent intestines on the bladder, that is, as the bladder is emptied, the intestines descend and take the place which the bladder, when distended, occupied; replacing it as a support of the uterus in front. The importance of this latter force is shown by the difficulty which some women experience in micturating in the recumbent posture. In some cases, and probably in a good many others besides those in whom it is noticed, when the bladder is emptied the uterus falls forward on to it, the intra-abdominal pressure being then exerted on the bladder through the medium of the uterus, so that in these cases there is anteversion present when the bladder is empty, but not when it is full. Above and behind, the uterus is in contact with small intestine, which often occupies Douglas's pouch. Different opinions have been expressed by surgeons in the habit of performing abdominal section, as to the frequency with which intestine occupies Douglas's pouch. I do not think observations made during operations of this kind are of much importance in showing what is the natural state of things, for the performance of an operation implies that there is something abnormal. With the bladder and rectum empty, and the uterus in contact with the rectum the position of the uterus is that described by Claudius as the normal one, namely, a position of retroversion, with the body of the uterus touching, or almost touching, the posterior wall of the pelvis. This Dr. John Williams (*d*) has designated the lowest normal position of the uterus, and has shown experimentally that the uterus when in this position, is raised and carried forward by filling of the rectum. But clinical experience shows that this "lowest normal position" of the uterus is not during life the usual position of the organ, even when the rectum is empty, and when this is the case, it must be supported by bowel behind, or else the pressure of bowel above and in front would force it into a position of retroversion. But for coils of intestine to support the uterus behind, it is not necessary that they should reach down to the very bottom of the pouch of Douglas.

Although there is no doubt that the position of the uterus may be influenced by repletion or emptying of the rectum with fæces, yet as a matter of fact we do not find as a rule the position of the uterus different when the rectum is empty of fæces, from what it is when filled with them. The fact is, that the rectum is seldom quite empty, when its contents are not fæcal, they are often gaseous, and the one is as capable of giving the support which in ordinary circumstances is sufficient to support the uterus, as the other.

The effect of the bladder, in modifying the position of the uterus, is greater and more easily perceived. When full it may carry the uterus far upwards and backwards as to place it beyond the reach of the examining finger. When empty the body of the uterus may so sink down upon the bladder as to become nearly parallel with the anterior vaginal wall. Fritsch has suggested that fæcal masses in the sigmoid flexure may press the uterus down into a position of anteversion, a view supported by post-mortem examinations in which the condition of things necessary to permit this has been found. This is far more important than many of the alleged causes of anteversion, although it cannot be perceived during life.

The vagina and perineum are sometimes spoken of as supports of the uterus. Whatever importance the vagina has as a support to the uterus is derived from the muscular and fibrous structures of the pelvic floor which are inserted into it. I believe that the relation of the vagina to prolapse of the uterus is more often causal than preventive. There is good reason to think that prolapse of the vagina often leads to elongation of the cervix and prolapse of the uterus. On the other hand, we can easily drag down the cervix uteri to the vulva, the upper part of the vagina readily undergoing inversion as we do so. I therefore dismiss the vagina from the list of uterine supports, otherwise than as a part of the pelvic floor.

The assumed function of the perineum as a uterine support requires notice, because it has been described in large language, and the description illustrated by some strangely inaccurate diagrams, in a popular text-book on the diseases of women. The only importance of the perineum with respect to prolapse of the uterus is this: When the uterus descends, it passes through the vaginal canal. The orifice of this canal is its narrowest part, and therefore here the uterus meets with some resistance to its downward progress. When the perineum is torn through, the vaginal orifice is made large, and does not offer resistance to uterine descent. The uterus must have already sunk to a considerable extent before it meets with resistance from the vaginal orifice, so that if this resistance were insurmountable, all that it could do would be to prevent prolapse getting beyond a certain stage. But as a matter of fact, the resistance which the vaginal orifice offers is soon overcome by the dilatation of that orifice. I have seen complete prolapse, the vagina turned inside out, and the whole uterus outside the vulva, contained in the inverted vagina, in a virgin. I have also seen a case in which, at the first and only confinement, twenty years previously, the perineum was torn quite through into the anus. The patient suffered from incontinence of fæces, but there was no prolapse, notwithstanding that the support of the perineum had been lacking for twenty years. Similar cases have been seen by other observers. They show that the intact perineum does not prevent prolapse, and that destruction of the perineum does not cause prolapse.

The structures which are called ligaments of the uterus, and which from their name might be supposed to fix it (excepting the round ligaments), are folds of peritoneum passing from the uterus to the walls of the pelvis. In the normal state these ligaments are never tense, and therefore they cannot be agents in maintaining the uterus in its normal position, although no doubt they help in resisting sudden prolapse. But, as we commonly see in the case of large hernias, the peritoneum soon stretches and slips before a continually acting force, and therefore the assistance which it offers to prolapse is soon overcome. Savage (*a*) has shown that when the uterus is pulled down there is a certain point at which its progress is stopped by the utero-sacral ligaments. These have been called the musculi retractores uteri, but the muscular fibres in them are so few, that they cannot have any appreciable action as muscles.

The round ligaments run in a gentle curve from the inguinal canals, under the peritoneum to the uterus. In a normal state of parts, they do not pull on the uterus. Fritsch (*b*) attributes the rising of the uterus during pregnancy to the traction of these ligaments. If they were tense they might in the first few weeks do so, but they are not tense, and if they were, their effect after the fourth month would be to prevent the uterus from rising further. I therefore do not believe that the

(*b*) *Lage Veränderungen der Gebärmutter*, s. 12.

pulling of the round ligaments has any appreciable influence on the position of the uterus during pregnancy. As the uterus grows, the round ligaments grow too, and suit themselves to it. It has been shown by the experience of operators, that the uterus can be pulled upwards and forwards by pulling on the round ligaments, and they are therefore to be reckoned as one of the obstacles to the greater degrees of prolapse. The absence of tension of these ligaments when the uterus is in a normal position, shows that the uterus is not suspended by them. They do not prevent prolapse, although they may oppose and retard its later degrees.

Seeing therefore that the so-called ligaments of the uterus are never tense so long as the uterus is not lower down than usual, and that the perineum may be destroyed without affecting the position of the uterus, it seems to me that we are driven to regard the pelvic floor as the essential uterine support.

Clinical Memoranda.

UNDEFINED DISEASE.

Case I.—*Purulent Sore Throat—Furred Tongue—Pyrexia—Anorexia—Debility—Typhoid Diagnosed?—Rapid Recovery—Full Diet—Chill—Severe Diarrhœa, troublesome in Checking—Recovery.*

By JOHN W. MARTIN, M.D., M.Ch.,
Sheffield.

This patient, Mr. P——, consulted me on the 11th of November, 1886. He is about 26 years of age, and unmarried. Constitutionally he is very gouty, and has had two severe attacks which laid him by for almost two whole winters. When seen he appeared to be suffering from the effects of a chill, and a severe cold. He complained of sore throat, and of being very weak. Examining the throat, I found it of a dusky red colour, very little tumefaction, and covered over with a slight nasty purulent looking secretion. Deglutition was very painful. The tongue was large looking, covered with a thick coating of white fur, and presented the ordinary appearances of a liverish looking tongue. The temperature was up to 101°; his visit to me was an evening one. There was no dicrotism in the pulse, no diarrhœa, or pain or tenderness in the abdomen. There was little or no variation between the morning and evening temperatures. His place of business is within the Rotherham district for water supply, and is low, lying close to the river Don. It is liable to being flooded during freshets on the river, and of necessity has a damp sub-soil. There had been a good deal of typhoid in the Rotherham district, and one of the leading employeés had not long before died of that disease.

Typhoid was clearly in my mind in studying the case, but the idea did not seem to be supported by the symptoms. Some kind of blood-poisoning had evidently taken place. Diphtheria was what I most feared. Though there was an abundant muco-purulent secretion covering the tonsils, at no time was there the slightest appearance of a membrane. Purgatives, diuretics, and gargles, improved the patient's general condition considerably, but the great weakness continued. The bowels acted regularly. The tongue was cleaner, but still presented the same evenly white furred appearance, very unlike the tongue usually seen in typhoid. There was no diarrhœa, gargouillment, or abdominal tenderness. Being in lodgings, and as he so far disliked giving trouble that he would not even ask for beef-tea, and other proper sick diet, to be prepared for him, I sent him home to London on the 15th November to be under his mother's care and nursing.

There the family medical man pronounced the case to be typhoid, though none of the usual train of symptoms appeared at any time when at home. By the 25th he was up out of bed, and eating freely of solid food. He had not the slightest relapse of any kind. Whilst at home, and lying at home, he felt himself doing well, and nothing very much the matter, beyond a steadily increasing desire for food. During the whole of December, and the Christmas holidays, he felt in excellent health, better than he had done for a couple of years.

He returned to Sheffield on the 5th of January. On the evening of the 8th, he again consulted me, greatly alarmed lest he might be suffering from a recurrent attack of typhoid. He had a slight sore throat, his bowels had been freely moved, without, however, the character of diarrhœa. He had taken a pill on the 6th, to the action of which he ascribed the loose state of the bowels. The tongue on this occasion, though still very far from presenting the typical characteristics of a true typhoid tongue, was more like one than on the former occasion. The pulse was weak and rapid, but otherwise a natural pulse; no dicrotism about it. Temperature 100°, the visit being paid in the afternoon. There was no abdominal pain or tenderness, and no trace of gargouillment. He looked well, and felt in all other respects very well. He was under observation from the 8th to the 14th, and remained during that time indoors. At first the following mixture was prescribed:—

℞ Potass bicarb., ʒij.;
Tr. aconiti, ♏xl.;
Aq. acetat. am., ʒiv.
Liq. morph., ♏xl.;
Syrupi, ℥j.:
M. Aquæ, ad ℥viij.

Sig.—Two tablespoonfuls to be taken with one of the powders, in effervescence, every 4 hours.

℞ Pulv. acid citric, grs. xij.;
Ft. pulv. mitte, viij.;

Sig.—"Powders."

Seen again the morning of the 10th. Throat felt much better. The looseness of the bowels had developed into a smart diarrhœa. Motions copious, loose, and painful when passed. Temperature 99°. Pulse 84. Tongue cleaner at the tip, still much furred at the back. Mixture stopped. Ordered—

℞ Tr. catechu, ʒij.;
Bismuthi carb., ℈ij.;
Mist. cretæ co. B.P. ad. ℥viij.
M. ℥j. every third hour.

Diet to consist of milk, with arrowroot, with bread soaked in it, sago, &c. No beef-tea or solids.

Visited again in the evening. Temperature 98·4. Other symptoms unchanged. Diarrhœa persistent, and very frequent. I ordered him to take ʒiss. of the mixture for a dose.

On the morning of the 11th no change in the condition of the bowels, or other symptoms. The tongue if anything more furred. Saw one of the motions, which was very fœtid smelling, soft, smooth, free from all lumps, looked bilious, but the natural colour was of course interfered with by the bismuth. I at once changed the treatment, and ordered—

℞ Acid sulph. dil., ʒij.;
Liq. morph., ʒj.;
Ext. ergotæ liq., ʒiij.;
Syrupi zingib., ℥j.;
Aquæ chloroformi, ad ℥viij.;
M. ʒj. every third hour.

At my evening visit I found he had had only one motion after the first dose, and none after the second. He felt a little desire to go still if he moved about much. Temperature 98°. Felt increased desire for food, and in every other respect very well.

On the 12th improvement continued. He was able to take some fish.

On the 13th, felt quite himself. On both these days, the temperature night and morning remained at 98° and 97·6°.

On the 14th he returned to business, taking a simple carminative mixture to allay a tendency to flatulence which still existed, but which, by the 16th, had ceased altogether.

Remarks.—This case appears to me to be one from which a good deal may be learned as to difficulties in making exact diagnosis. There can scarcely be a doubt, that in the outset, the case was the result of some malign miasmatic influence. The nasty pus-covered sore throat, and extreme debility, with pyrexia of an asthenic type, all point clearly in this direction. Facial appearance and expression, character of the tongue, and want of dicrotism in the pulse, together with the absence of diarrhœa, did not allow of one's committing oneself to the idea of true typhoid, an opinion, to my mind, much strengthened by the subsequent history of the case. I have never, so far, seen such a condition of the throat in cases of straight-going gastric catarrh, or gastro-enteritis. The absence of gastric or other abdominal pain, nausea, vomiting, or diarrhœa threw difficulties in the way of determining the nature of the case as one of these two complaints. Typhoid was favoured by the district in which he worked being affected, and by the fact of one of the employeès connected with the works having died from that complaint. From the general symptoms, I felt inclined to regard it more in the light of abortive diphtheria, if such there can be. The great soreness of all the muscles about the pharynx, the absence of much tumefaction, the character of the secretion covering it, and the extreme debility, favouring this view. At the time he again came under notice, the question was put, "Is there *any* chance of my present condition being due to a recurrence of what was pronounced to be typhoid in London?" There was on this occasion loose bowels, developing into diarrhœa, the motions being very fœtid, there was also pyrexia, and the character of the tongue was much more like what is seen in typhoid. There was pain and tenderness about the bowels, and, altogether it was impossible to express a decided opinion, though one felt tolerably certain it was not typhoid. The patient's perfect recovery in a few days of course made it impossible that it should be so. In London, after being a few days at home, *i.e.*, about the 18th, the case was pronounced to be typhoid, and yet some eight days after he was allowed full diet, consisting of solids of various kinds, and by the end of the month he was going about quite himself. For my own part, I feel the strongest doubts as to the case ever having been true typhoid, and, if it were, I certainly never would have ventured to place the patient so soon upon such a diet. The longer one lives and practices, the more one meets with what may be termed "border-land cases of disease," in which exact diagnosis is extremely difficult, or impossible, and in which all that can be done is carefully to recognise the symptoms, special and constitutional, present, and without expressing any decided opinion, deal with them on general principles. Some men find it good policy to give it a name, and stick to it, and there is much to be said in favour of such a course on grounds of policy, but it is not quite so satisfactory if two men are dealing with a case at a distance from one another, and independent one of the other.

DIFFICULT PARTURITION—PROTRUSION OF THE UTERUS WITH UNDILATED OS UTERI.

By MARTIN O. CARROLL, M.Ch., L.M., T.C.D.,
St. Vincent, West Indies.

The following case will, I think, be interesting to your readers:—On Jan. the 28th, 1883, at 8 p.m., I was sent to attend an unmarried black woman, named Georgiana Dolphin, who was in labour with her first child. I found the labour pains very weak, and no dilatation of the os whatever. I accordingly returned to my house which was close by; at 11 p.m. I was sent for again, and on arriving found the pains very strong, and with scarcely any intermission between them. On examination I found the uterus protruding fully two inches outside of the vulva, the os was nearly impervious, and it was only by using a boring motion I could succeed in getting the little finger of my right hand into it, in the same way I got in the little finger of my left hand, and then by drawing them asunder I dilated the os sufficiently to admit of the introduction of both my first fingers, and after considerable difficulty the two first fingers of each hand, but do my best I could not dilate the os any more; the labour pains all this time were getting stronger and stronger, and the uterus protruding more and more so that it appeared as if the woman would have expelled it altogether; by using all my strength I succeeded in tearing open the uterus with my fingers, and delivered with the forceps; having removed the placenta, the uterus having contracted well I pushed it back into its place, put the woman for a few days on small doses of opium, and in two weeks she was up, walking about.

On the 18th day of this month (Jan., 1887) I made it my business to see the woman before publishing these details, she told me she had not had a child since, and has not suffered from any prolapse of the uterus, and, in fact, has never had a day's illness from any cause whatever.

Transactions of Societies.

ACADEMY OF MEDICINE IN IRELAND.

SURGICAL SECTION.

Meeting held Friday, January 21.

The President, Sir William Stokes in the Chair.

TREPHINING FOR MASTOID DISEASE WITH PARALYSIS AND APHASIA.

Mr. **Fitzgibbon** read a paper on a case of trephining for mastoid disease with paralysis and aphasia:—Miss A. E., æt. 27, was attacked by an ear-ache on the left side, in May, which continued for several weeks, when facial paralysis set in on the affected side. This symptom disappeared, shortly after facial paralysis appeared on the right side, with confusion of ideas and aphasia, and threatened loss of power of lower limbs, indicating intracranial mischief. He trephined the left mastoid cells, removing a portion of upper surface of petrous portion of temporal bone. After some days matter escaped from the opening in the bone, and the patient finally recovered perfectly both her physical and mental health.

The **President** said the case illustrated the importance of bone-drainage, the subject of which was discussed last year. He asked whether the suppuration was from an abscess or from the tract of the wound made by the trephine; and, secondly, whether the paralytic symptoms resulted from local inflammation of the bone itself, or, possibly of the periosteum?

Mr. **Wheeler** said that the night he himself saw the subject of this communication she was suffering from want of power in the lower limbs; she misapplied words, and had facial paralysis on the right side. Her history was, that an attack of scarlatina, some years before, was followed by discharge from her left ear. Having examined her ear by artificial light he perceived an aperture in the upper part of the tympanic membrane, and he was informed that a short time before there had been a discharge from the ear, which suddenly ceased. The temperature was high and the pulse rapid; the pupils responded equally, but he had no opportunity of making an ophthalmoscopic examination. He came to the conclusion that she was suffering from phlebitis perhaps a slight meningitis, and not improbably from an abscess in the tempero-sphenoidal lobe. His reason for thinking that an abscess might be present was that the train of symptoms and her history almost exactly corresponded to those of a patient of his own on whom he operated and successfully evacuated an abscess situated in the tempero-sphenoidal lobe, as reported to the Academy of Medicine some four years ago. Two symptoms very characteristic of intracranial abscess were absent—viz., abnormally slow pulse and abnormally low temperature. But the existing phlebitis and meningitis would account for this. The want of power in her lower limbs was due to irritation of the medulla oblongata, perhaps a local phlebitis of the vessels of the medulla, as the acoustic vein joins the veins on the anterior surface of the medulla oblongata. The facial paralysis on the right side was probably caused by the irritation of the centre of the seventh nerve, carried from the left side, as the centres of both nerves lie close together. The defect in speech was likely due to the fibres of the left restiform body running upwards. At the consultation he strongly advised operation. Although Mr. Fitzgibbon stated he placed the trephine a little higher up than that designated in the operation he (Mr. Wheeler) performed, on examination of the bone removed it would be seen that the mastoid cells had been opened, which would not have been the case had the trephine been placed higher up. Some persons thought that there was danger in opening the lateral sinus, but if the rule were adopted as laid down by him (Mr. Wheeler) there could be no danger of it—namely, first to bisect the mastoid process, all anterior or in front of the line keeping the operator well clear of the lateral sinus, and then to place the lower border of the trephine on a level with the external auditory meatus; the tympanum and mastoid cells would be opened, giving free exit for discharge; the dura mater would be exposed, and should pus exist between it and the cranium there would be freedom for its escape. Further, should an abscess exist in the tempero-sphenoidal lobe of the brain it might be conveniently tapped through the exposed dura mater or through the tegmen tympani should it not have burst through this slender portion of bone. Sections of the skull and brain which he exhibited demonstrated, he said, on the right side the operation which he performed; and on the left side, having first performed the operation, he removed the cerebellum to show that there was no danger of wounding the lateral sinus. He also perforated the dura mater exposed in the operation, and penetrated through it the tempero-sphenoidal lobe of the brain with a probe *in situ*. Hence, to tap an abscess in the sphenoidal lobe was the direct and correct course to adopt. The perforation in the tympanum was insufficient to evacuate the discharge in cases suitable for trephining,

Mr. Story failed to see what object was gained by trephining the mastoid at all, since pus was found nowhere. Of course, if the surgeon made up his mind that he had to take something out by trephining, let him do the operation, but he ought not to make a hole in the temporal bone to seek for pus and find none. The favourable termination of the case appeared to be a *post hoc* instead of a *propter hoc*, as regarded the *hoc*. Another point was that he did not see why the left ear was trephined instead of the right, as the lady had a running from both ears after scarlatina, and had paralysis of the facial nerve on the left side. The case was not to be regarded as one of those which would have died if left alone.

Mr. Pratt said he had seen eight cases of the kind. Of these four were operated on and recovered, while, of the others, two that were not operated on died, and he lost sight of the third. Moreover, pus welled into the wound when made by the trephine only in one case, but the pus that came afterwards appeared to come from inside the skull rather than from the wound itself. Hence the advisability of the operation. He asked how Mr. Fitzgibbon stopped the hæmorrhage?

Dr. Cox mentioned the case of a female whom he treated medically for similar symptoms, and she became restored to health. He asked how Mr. Fitzgibbon accounted for the paralysis, especially of the lower extremities, and whether he attributed the unsteadiness of gait to cerebral causes?

Mr. Thomson inquired at what period after the operation was performed did recovery result? because after the removal of the bone there were several days during which there was no discharge, and as the history of the case went on there did not seem to have been any great improvement for several weeks. If the opening had given an exit to any collection of pus, once the pus escaped there ought to have been some definite improvement. But the case seems to have covered a very long period, with fluctuations.

Mr. John H. Scott asked whether the purulent discharge had a strong fœtor?

Mr. Bennett said the tendency of Mr. Wheeler's remarks was to recommend trephining as a remedy for all cases of otorrhœa.

Mr. Wheeler said that he had distinctly defined the suitable cases, and indicated that there were many cases unsuitable.

Mr. Bennett enumerated several not relievable by the trephine, including pyæmia and the direct perforation of the lateral sinus by caries, and his opinion was that the only cases likely to be relieved were those in which the operation was done early for accumulation of pus in the mastoid cells, or where, with a bold stroke, an abscess of the brain was reached.

Mr. Fitzgibbon, in reply, said it was with the view of acquiring information himself on some of the questions discussed that he had brought the case forward. He attributed the paralysis to inflammation extending, in the first instance, to the facial nerve upon the left side, and the paralysis on the opposite side of the brain. The loss of power in the lower extremities was due to inflammation extending to the medulla oblongata, arising from the pus between the dura mater and the bone on the left side of the cranium. The granulations which he had described, but which Mr. Wheeler had not observed, might have been blebs of purulent matter which looked like granulations. At all events, they would not wipe off with wadding. He had placed the trephine above the mastoid process, trephining the petrous portion of the temporal bone, but involving the upper margin of the mastoid process; and the demonstration given by Mr. Wheeler justified the precaution he took in that respect, because a great deal more than half the disc of the trephine was involved in the petrous portion of the temporal bone, and the separation of that large mass would require a greater amount of force than might be required to give free exit to pus, and might extend so as to lacerate the lateral sinus. Mr. Story's question as to what was gained by the operation, since no pus was got out, had been answered sufficiently by Mr. Pratt. Believing suppuration had taken place before inflammation between the bone and the dura mater, which became extravasated on the occasion of a long carriage drive, thereby relieving the pressure, he had trephined in the position where the pus was most likely to present itself. That condition explained the paralysis on the left side, and paralysis supervening on the other side was from the extension of the inflammation to the nerve on the opposite side from the common origin. It was, however, clear that the surgeon should not let the patient die for want of making an effort to save life; and in the case under discussion Dr. Mayne had expressed the opinion that the girl must die, while believing that the operation could do no good. Hence the operation was justifiable, even though the indications were extremely ambiguous and questionable. The hæmorrhage was stopped with a piece of lint by putting his finger on it. Relief was given when he gave the pus free exit. The inflammatory condition had been going on, extending to the base of the brain, to the meninges and the medulla oblongata, and was subacute at the time of the operation; but the pain was relieved immediately the matter commenced to discharge through the trephine opening, and she never complained of the agonising pain in her head which she had done for a considerable number of days following the operation. The symptoms were generally relieved immediately after the operation, with the exception of great prostration and delusions, which took possession of her even when her physical condition was that of convalescence. There is an unpleasant fœtor from the discharge; it was more offensive than laudable pus would be. As to Mr. Bennett's objection to trephining in all such cases, he had himself the case of a woman named Margaret Robinson in which Mr. Wheeler would have trephined, but the milder operation of incision answered the purpose quite as well. It is a well-known fact that the incision of inflamed bones often led to the recovery of a bone which otherwise would go on into destructive caries.

The Section then adjourned to the 18th February.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

A Special Meeting was held on Wednesday last, February 16th, for the discussion of

EMPYEMA IN ITS MEDICAL AND SURGICAL ASPECTS.

The President, Prof. Grainger Stewart, M.D., in the chair.

The discussion was opened by Dr. William Russell, who detailed the treatment and progress of six cases which he had had recently under his care. He had much faith in a carefully conducted system of drainage for the usual run of cases. He was in the habit of making a double opening, through which was passed a continuous drainage tube. This afforded the freest outlet for the purulent effusion. This was an operation which every physician ought to be able to undertake. In cases of longer standing resection of a considerable portion of the thoracic wall might be necessary. This belonged more properly to the sphere of the surgeon.

Dr. Caverhill thought that sufficient care had not been bestowed on the after treatment of some of these cases. He exhibited two cases, where operative interference had been successful. In one of these he had instituted a most careful system of after treatment, with the view of obviating deformity. The result was most encouraging. It was a mistake to suppose that the appearance of pus necessarily indicated the presence of organisms. In one of his cases, where he had used the spray throughout, the pus had been repeatedly examined in the bacteriological laboratory with negative results.

Mr. John Duncan said they must treat an empyema as they would an abscess, and evacuate the pus. As in the case of the abscess, there were three possible lines they might follow:—Aspiration, drainage, resection. Before predicating too much as to aspiration, they must have a better understanding why the pus was formed. Pathologists had yet much to discover in this field. His own experience led him to distrust aspiration in the treatment of abscess. Similarly it appeared to him of limited efficacy in empyema. In recent cases, however, it might be tried with advantage. If of no further value it might possibly lead to encystment. Drainage had a much wider field of application. If the cavity were kept aseptic, and the drainage free, there was good chance of its being successful in young subjects, especially when the collection was encysted. There was no need for more than one opening. Its position must not be too low, else drainage was impeded, owing to the elevation of the diaphragm. The removal of a small portion of rib was an obvious advantage in the way of protecting the tube from pressure. For old-standing cases, however, especially those where the cautery was no longer aseptic, or where the lung was firmly tied down, their only hope lay in resection. They must resect freely, say, a portion of eight or nine ribs from the third downwards. He had operated thus in six patients, in three instances with complete success, and in three with partial success.

Dr. **Affleck** endorsed Mr. Duncan's statement that they must have a more exact pathology of the empyematous condition. It arose evidently in connection with varying forms of depreciation of the system. He had recently had a case, where a serous effusion of some standing became purulent after scarlatina. The diagnosis of an empyema was no easy matter. Most of the signs and symptoms which had been emphasised proved alternately fallacious. He thought more might be made of the peculiar cough. Though he had never seen it mentioned, he felt sure the cough in empyema had a markedly different tone from that in simple serous effusion. The treatment must, of course, vary with the condition and the causation.

Mr. **Hare** referred to some recent French observations, which went to prove that most pleurisies were ultimately tubercular in origin. This was of interest in connection with the preparation which Dr. Woodhead submitted at their last meeting. Probably at the present time, there was too great a tendency to adopt the severer forms of operative interference. The resulting deformities were sometimes most serious. In the selection of their line of treatment they must be guided by reason, and not merely by fashion.

Dr. **James** discussed the physical conditions which favoured the reparative process in the retracted lungs. Both inspiration and expiration were of value. Tapping had a wider range of application than was usually accorded to it. If it were only adopted early enough and used at sufficiently short intervals, they would have more success. They must not delay the second aspiration till the fluid has re-collected. The best site for puncture was between the fifth and sixth rib, rather behind the mid-axillary line. At this point, experiment had shown that the level of the fluid was highest. The association of tubercle with pleurisy was still a point which required definition. He had observed the peculiar cough, to which reference had been made, and attributed it to the increase of intra-thoracic pressure.

Mr. **Alex. Miller** agreed that much had to be done in elucidation of the causation of empyema. He had always believed that micro-organisms were necessarily present, but Dr. Caverhill's remarks seemed to point towards a negative possibility. The best point for puncture was as high as the third interspace. Post-mortem examination proved how high the diaphragm might reach in such cases.

Dr. **Hadden** believed in the efficacy of early tapping in pleurisy with effusion. If such cases were carefully watched and treated in the venous stage, there would be few empyemas, and little need for surgical interference.

Dr. **Napier** emphasised the absorbent powers of the venous surfaces. Probably mechanical interference explained, in some instances, the occurrence of the empyema. In his experience, large venous effusions were often absorbent quite apart from aspiration. Of course, his observations were made on the healthy country child. It might be difficult among town and especially hospital patients. He had been struck with the not unfrequent association of empyema and puerperal conditions.

Dr. **Hunter** said that the withdrawal of a certain amount of fluid undoubtedly aided nature's effort at absorption.

Dr. **Bramwell** spoke of the difficulty of diagnosis. More particularly in the young child might have a considerable collection of fluid and auscultation reveal nothing very abnormal. There was little doubt that empyema in the young child was frequently due to a superficial patch of localised pneumonia. In such cases, aspiration was of much value. In graver cases he was inclined to favour a system of continuous drainage on the syphon principle. This ensured the gradual withdrawal of all the fluid with a commensurate expansion of the lung. It obviated the chief object to resection, the opening up of the closed pleural cavity.

Dr. **Brakenridge** thought the fact of an occasional dependence of an empyema on localised patches of caseating pneumonia below the pleura introduced an element of considerable danger in attempting to aspirate. He had seen cases where the empyematous state was, if not produced by, certainly kept up by aspiration.

Dr. **Sinclair** thought the expiratory phase of distinct value in the curative process, as regarded the retracted lung, and cited the case of a cornet-player, who only recovered health after operation, when he was allowed to resume his playing.

◆

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Friday, February 4th, 1887.

The President, Dr. **Alderson**, in the Chair.

LIVING SPECIMENS.

Mr. **Keetley** showed: (1) A case of cholecystotomy; (2) a case of arterio-venous aneurism of the cavernous; (3) sinus after treatment by compression.

ON THE NATURE AND TREATMENT OF HYPERTROPHIES AND TUMOURS OF THE NASAL AND PHARYNGEAL CAVITIES.

Dr. **Thudichum** read a paper on this subject. He related a number of cases of hypertrophy of one or other, or both lower turbinated bones, causing respiratory inadequacy and its consequences to lungs, nerves, and constitution. He showed how it led to malformations of the septum, and to its ulceration, perforation, and loss. He showed how these cases had been cured by the abscission of parts of the lower conchæ. He also related cases of hypertrophy, and of abscesses in the middle concha, and in the ethmoid cells, and how they had been cured by the ablation, either of the entire conchæ, or of a portion of the cells. He further gave an instance of the simultaneous or independent ablation of excrescences of the septum, all of which had yielded satisfactory results. He objected to surface cauterisation of the nose, and gave cases illustrating its results. In one case, that of an officer, surface burning in 27 sittings, had produced severe ashmatic attacks which only yielded after the ablation of the concha. He referred to the great variety of nervous symptoms connected with nasal hypertrophies, and to their disappearance after ablation of the hypertrophied parts, and put it as a general fact, that in cases of chronic hypertrophy of any of the four, respectively six or eight, turbinated bodies, causing obstruction or accompanying neurosis, ablation was indicated, and was in most cases the only means of effecting a cure. He gave several instances in which members of our profession had not only introduced and accompanied patients who had been so restored to health, but had themselves undergone such operation with results highly satisfactory to themselves. He showed how this refuted the observation which in the course of last year had been made in a medical journal, in which it was reported that a conclave of specialists at Brighton had declared such operations to be either unnecessary or unjustifiable, and had termed their result a mutilation. He maintained that these observations were not based upon any experience. The mutilation consisted in the existence of disabling disease, and its removal was the only cure. He believed that the profession would not place the slightest confidence in such imaginary objections. He alluded to a lecture by Dr. McBride, of Edinburgh, on nasal reflex neuroses, and showed that the literary quotation then given began only with 1881, while he, Dr. Thudichum, had taught the whole subject of reflex neuroses, from nasal disease, particularly asthma, hay fever, hemiopsia, convulsive twitchings, spasm of pylorus, perverted sense of smell, vertigo, loss of consciousness, cough and spasmodic sneezing, ever since 1875. He showed that both nose disease and neurosis or nerve complaint have a common dyscratic origin, and can be cured fundamentally only by the combination of operative and general treatment and not by either alone. He further showed that without such a constitutional basis the more serious reflexes, except sneezing, were never produced. He denied that the nose contained erectile tissue, or an erectile apparatus, and maintained that the word erectile was inappropriate to the parts of the conchæ provided with a multiplicity of venous sinuses. He maintained the superiority of the electro cautery proven to all other operative procedures, and quoted cases as proofs. One had been two and a-half years under forceps treatment in several hospitals in succession, but had been cured by electricity in two sittings. Another case was found to have two inches of steel wire fixed in his nasal cavity, being the residue of a broken snare unsuccessfully used eight months before. He also described the advantages of the use of cocaine, and the disadvantages of the use of general anæsthesia in these cases. He concluded with a novelty, namely, the proof of the permeability of the incisive canal, and showed that great attention must be given to all the foramina of the cavities adjacent to the nasal cavity, of which foramina there were no less than sixteen. The cases were illustrated by sketches on the black board.

Mr. **Spencer Watson** asked for further information with regard to the removal of the spongy bones with the actual cautery, and whether the platinum cautery would pass through the bone ?

Dr. **Clippingdale** did not agree that asthma was a neurosis dependent upon obstruction of the nose by polypi.

Dr. **Ball** said that there were many cases of chronic hypertrophic rhinitis which were curable without involving the removal of the spongy bone.

Mr. **Collyer** asked if general anæsthesia was used by Dr. Thudichum in his cases ?

Dr. **Bennett** would like to know whether there were any marked signs of syphilis in Dr. Thudichum's cases ?

Dr. **Newton Pitt** asked Dr. Thudichum if he had found any bacilli in any of his cases which he had described as tubercular ?

Mr. **Lloyd** inquired if hæmorrhage had ever proved troublesome after the operation ?

After some interesting remarks from the President, Dr. **Thudichum** in reply described in detail his method of removing the inferior turbinated bone with the electro cautery.

MULTIPLE NEURITIS AFTER DIPHTHERIA AND UNILATERAL PROGRESSIVE FACIAL ATROPHY.

Dr. **Campbell Pope** read notes of two cases under this title, each of which was contributed by Dr. C. W. Suckling. *Case* 1, was that of a woman, æt. 42, in whom the disease commenced when she was about eighteen years of age. Left side of face markedly smaller than right. Bones much atrophied. The horizontal ramus of the lower jaw is one inch shorter on the left than on the right and much diminished in thickness. The malar bone is also much atrophied. The fat is quite gone and the left eye being sunken and well marked fossæ being present above and below the zygoma. The skin is not altered in colour but the eye-lashes are scanty and there is complete alopecia over the left half of the front of the skull, this was concealed by her at the time she was photographed. The temperature is a degree higher on the left side; sensation is unaffected. Two well marked grooves are present on the left side of the forehead, due to atrophy of the face in the situation of the supra-orbital nerves. The general health is unaffected. The tongue, soft palate, and hard palate are normal, and there is no atrophy elsewhere. The faradic response is much increased on the left side, evidently owing to diminished resistance of the skin, &c. No cause can be assigned, but she had toothache a great deal when younger, and she thinks her face has got worse after her confinements. No syphilitic history.

MULTIPLE NEURITIS AFTER DIPHTHERIA.

Case 2.—A young man was admitted into the Queen's Hospital, Birmingham, three months ago, with almost complete paralysis which had commenced in the legs, and later on had affected the forearms. Ten weeks previously he had had a sore throat, his sister living in the same house died of diphtheria, and his larynx was anæsthetic on admission. There were well marked dropping of the hands and feet, emaciation, marked tenderness in the calf muscles, and along the nerve trunks. He suffered from shooting pains before admission. A prick of a pin caused two sensations, touch being first perceived and pain after. There was also some algesia. The reaction of degeneration was present in the extensor muscles of the legs and forearms. He is now improving gradually, taking forty minims of the liquor strychniæ three times daily, and being galvanised and rubbed. Faradic response has returned in the thecar and hypo-thecar muscles and in both forearms.

An interesting discussion followed, in which the President, Dr. Bennett, Mr. Mallan, Dr. Pitt, Dr. Blenkinsop, took part, and Dr. **Pope** replied.

CARD SPECIMENS.

The following were shown by Mr. H. **Percy Dunn** :—(1) Extensive rupture of the duodenum, following a kick from a horse. (2) Tuberculosis of the spleen from a child of three months. (3) Sarcoma of the testis. (4) Large intussusception from a child.

Dr. **Abraham**, some microscopical sections of sponge grafts.

◆

SESSION OF
The General Medical Council.

TUESDAY, February 15th.

The President, Sir Hy. W. **Acland**, Bart., in the Chair.

After the customary formalities on the introduction of new members, Dr. **McVail**, of Glasgow, desired to raise a question on a point of order as to the election of certain members by the Senatus Academicus of the Scotch universities, but this was over-ruled by the President on account of the requisite notice of motion not having been given. The President then delivered his annual address, which partook principally of the nature of a survey of medicine in its development and changes during the fifty years of Her Majesty's reign, and the acts and functions of the Council during its existence. The address was necessarily of great length, and we regret we have not space for it, owing to the great pressure of other matters. After its delivery the necessary routine questions and appointments of committees were gone through.

On the presentation of the table showing results of professional examinations held in 1886 for qualifications granted under the Medical Act by the bodies named in Schedule A of the Act, and one showing results of preliminary examinations in 1886, compiled by the registrar from such returns as have been supplied by the examining bodies, pursuant to the Council's request,

Dr. **A. Smith** called attention to the fact that the Apothecaries' Society of London had passed 214 candidates and rejected 447, and that the Faculty of Physicians and Surgeons of Glasgow had passed 65 and rejected 159. These results, he said, showed either that the examinations of the bodies in question had become much more stringent or that the education of the candidates was very defective.

Mr. **Macnamara** called attention to the circumstance that in regard to the highest percentage of marks obtained by the candidates, several of the universities had stated that information could not be supplied, and he urged the desirability of returns being made as to the lowest amount of information considered satisfactory by the examining bodies in preliminary education.

A table was also presented showing the number of exceptional cases that occurred during the year 1886 in regard to the length of the course of professional study, together with a statement of the action taken thereon by the several licensing bodies; and another table showing results of professional examinations held in 1886 for qualifications granted under the Dentists Act.

Dr. **Struthers** said it would be observed that the number of exceptional cases had greatly decreased since last year. The only bodies in which they had occurred were the Royal College of Physicians of London and the Royal College of Surgeons of England, in which the number of cases was 39 and 22 respectively. The number seemed to be large, and to require some explanation.

Sir Dyce Duckworth said that the cases that had occurred in the College of Physicians related chiefly to Colonial graduates. Only three or four had come from foreign universities, and in those cases the diplomas had been closely scrutinised, not only to ascertain that they were themselves genuine, but that the education was satisfactory.

VISITATION AND INSPECTION OF EXAMINATIONS.

Mr. Marshall, in bringing up the preliminary report by a subcommittee of the Executive suggested that the subject was so urgent and important that it ought to be dealt with by a larger body than the Executive Committee; and he proposed that the subject should be referred to a committee of the Council for consideration and report during the present session.

After various suggestions and modifications the following motion was put and agreed to:—"That Sections 2 and 3 of the Medical Act of 1886, together with the preliminary report by Dr. Humphry and Dr. Quain, on the Visitation and Inspection of Examinations under the Medical Acts of 1858 and 1886, with certain suggestions by Mr. Simon for the Council's future Inspections of Examinations, and the recommendations by the Executive Committee, be referred by the Council to a Committee to report on the subject to the Council at its present session."

The committee was then appointed, and Mr. Marshall was requested to act as chairman.

Mr. Marshall brought up various communications on the subject of diplomas in Sanitary Science for entry on the Minutes. He stated that the schemes and curricula all coincided in requiring that the candidates presenting themselves should be registered practitioners, and in some instances the candidates were required to be graduates in medicine of the university giving the diploma, or of some other body.

A communication was received from the University of New Zealand, applying for the recognition of its diplomas. It was ordered to be entered on the Minutes.

Communications were also received from the Apothecaries' Hall of Ireland, and the King and Queen's College of Physicians in Ireland, with reference to a conjoint scheme of education and examination, and ordered to be entered on the Minutes.

The remainder of the sitting was held with closed doors.

WEDNESDAY, FEBRUARY 16TH.

Sir Henry Acland, President, in the chair.

THE APOTHECARIES' HALL OF IRELAND AND THE CONJOINT SCHEME.

Dr. Struthers brought forward the following motion: "With reference to the 'scheme for constituting an Examining Board in Ireland by the King and Queen's College of Physicians and the Royal College of Surgeons in Ireland,' received and entered in the Minutes of Nov. 20th, 1886, page 154; and to the communications to the Council from the King and Queen's College of Physicians in Ireland of Nov. 10th, 1886, and the Apothecaries' Hall of Ireland of Nov. 9th, 1886, received and entered in the Minutes of Nov. 9th, 1886, page 145; and to the 'Remarks,' with Appendix, by the King and Queen's College of Physicians, of date Dec. 31st, 1886, transmitted to the President by the College on Jan. 5th, 1887, and the 'Comments' thereon by the Governors and Court of the Apothecaries' Hall of Ireland, transmitted to the Registrar of the Council on Feb. 3rd, 1887, and received and entered in the Minutes of Feb. 15th, 1887: that the Council request the King and Queen's College of Physicians and the Royal College of Surgeons in Ireland to reconsider the scheme, in the strong hope that they may be able to arrange with the Apothecaries' Hall of Ireland a scheme which shall include the Apothecaries' Hall with the two Colleges." He said he did not appear in any way as a special pleader for the Apothecaries' Society, but as performing what he considered a public duty. It was somewhat difficult to frame the motion because there was not now before the Council any motion for the approval of the scheme; but they had the scheme on their Minutes, and therefore could deal with it. The motion was simply that the Council should advise the two Dublin Colleges to reconsider the scheme with a view of admitting the Apothecaries' Hall into a triple scheme. If the apothecaries were left out of the scheme what was to happen? By the Act of 1886 it was provided that a medical corporation might apply to the Council to have examiners appointed, and if the Council declined to do so the body might go to the Privy Council, and if it appeared to the Privy Council that the General Council had failed to secure the maintenance of sufficient examinations, or that occasion had arisen for the General Council to appoint assistant examiners, then the Privy Council might notify their opinion to the General Council, and if the General Council failed to comply with such directions of the Privy Council, the Privy Council might themselves appoint assistant examiners, and the Apothecaries' Hall of Dublin might be started as a new and independent licensing body for medicine, surgery, and midwifery. That was the prospect before them, and if that were the case they might have the profession in Ireland and England flooded with practitioners, whatever their professional knowledge might be, under the name of "apothecaries." This question had been discussed very elaborately on former occasions by the Council; and in 1863, in answer to an application from the War Office, the following resolution was agreed to: "That this Council is of opinion that the registered licentiates of the Apothecaries' Company of Dublin are as apothecaries entitled to practise medicine in Great Britain and Ireland." The result was that the army and other boards received the apothecaries' diploma on the same footing as any other medical licence. After tracing the history of the establishment of conjoint examinations, he said that the other Colleges of Physicians and Surgeons must make up their minds to part with a few of their privileges and fees, and that the examinations must be made, though upon "reasonable terms." He made the motion on three grounds: first, as a measure of justice due to the apothecaries; secondly, as a matter of expediency to the other bodies; and thirdly, as a public duty. It was not for the interests of the public that these bodies should be tolerated as independent licensing bodies, flooding the country with practitioners with their name and qualification. He moved this as a measure of peace. If they had the three corporations united into a conjoint board, they would have an end to contention; if not, it would be every man for himself.

Dr. Bruce seconded the resolution.

Mr. Simon, in supporting the motion on the ground of the demands of public duty, asked if any reasonable person could say that it was for the public interest that a separate and competing examining board should be set up in Dublin? In proportion as the College of Physicians felt itself stronger and higher than the Company of Apothecaries, it was bound to adopt the course urged upon it. *Noblesse oblige.* They ought not to allow any narrow personal feeling to stand between them and the completion of a scheme that would be for the general good of the country. It could never be for the public benefit that the two corporations should force the Company of Apothecaries into a position in which they would have to take refuge in the power of the Privy Council or the Medical Council to appoint assistant examiners. The Apothecaries' Company had been legally recognised, whether wisely or not, as a medical authority, and the question was whether they were prepared to assent to a course which would make that body a competing authority against the two Colleges in Dublin.

Mr. Wheelhouse heartily supported the proposal of Dr. Struthers, believing that if the Apothecaries' Company were not admitted to the conjoint examination infinite harm and mischief would be done.

Mr. Teale and Dr. Banks also supported the motion, and Sir William Gull said that the same principle would equally apply to this side of St. George's Channel. The Apothecaries' Company had a distinct function to perform, and on public grounds, therefore, it ought to be maintained. The Council, he thought, would stultify itself if it did not adopt the motion of Dr. Struthers.

Dr. Glover said that recent legislation did not contemplate the destruction of existing bodies, but rather their continuation. As therefore the number of bodies could not be diminished, the only hope they had was in their fusion. With that view, and believing that, after all, the pharmaceutical side of medicine was very important, perhaps more important than ever, he was quite prepared to give a hearty vote in favour of the motion of Dr. Struthers.

Dr. Kidd said that the feeling of the profession in Ireland was that the three bodies ought to be fused, and that it would be a very serious injury to the community if a body were established to compete with the two Colleges in their conjoint scheme. Such a rivalry would be a competition downwards, and not upwards. He did not see how the dignity of the College of Physicians was affected. The intention of the Act of 1886 was to include the Apothecaries' Hall in any conjoint scheme, and it was the duty of the Council to encourage such inclusion.

Sir Wm. Turner said Dr. Struthers' statement was so convincing that he felt there was nothing left for him but to support the motion. There was one aspect of the case which was of very great importance—viz., what was in the mind of the legislature as regards this question when they framed the Act of 1886? They necessarily put into the front rank that which they considered to be the most important, and that was "combination." The mind of the legislature was that combination should take place whereever it was possible, but that if through any difficulty combination did not take place, then that a body which could show that it was doing its duty efficiently should not be extinguished. What, therefore, they should urge upon the bodies was that they should strive to carry out what he believed to be the prime meaning of the Act, and that the alternative proposition should not be required to come into operation if combination could be performed.

Mr. Collins hoped that the Council, if it passed this resolution, would also pass a resolution of which he had given notice—that they should nominate one examiner in surgery for the Apothecaries' Hall of Dublin, which he represented. If this was not done, and the recommendation of the Council was not adopted, the effect would be that that body would be disfranchised, at any rate till the next meeting of the Council in June.

Sir Dyce Duckworth said he could not follow Sir William Gull in regarding this question as having brought before the consideration of the Council the other question which had to do with London. The question of the Apothecaries' Hall in Dublin and its relation to the Royal College of Surgeons, was not at all on all fours with the question of the relations of the English bodies. The action taken by the London Colleges was perfectly well known; it had been taken after very full and careful deliberation.

Mr. Macnamara said, as a representative of the College of Surgeons in Ireland, he might say that the College had on several occasions gone to the College of Physicians to represent the justice of admitting the Apothecaries' Society into the conjoint scheme. He thought the resolution proposed by Professor Struthers, and for which he would vote most heartily, was a most desirable one, and it would be a sad thing if the College of Physicians would not listen to the voice of the Council on this point.

Dr. Aquilla Smith after quoting from evidence given by Mr. Macnamara in 1874 that he considered the present system of licensing in Ireland had been attended with a paralysing effect on the promotion of pharmacy, and that the Apothecaries' Company had abnegated their functions in becoming examiners in medicine, he proceeded to give an account of the proceedings taken by the two Colleges in reference to the application of the Apothecaries' Company to be admitted to the joint examination. When the application was received the Council of the College of Physicians held a special meeting, at which it was decided, *nem. con.*, that the Council of the College regretted its inability to accede to the proposal, because it believed that the intentions of the Medical Act were best carried out by the arrangement that had been made in accordance with that in force in England. Under the circumstances he thought it was hopeless to send the matter back to the College of Physicians for reconsideration.

Mr. Brudenell Carter said he thought it would be unworthy of the dignity of the Council to address a petition to the College of Physicians the prayer of which it had no legal power to enforce; he was therefore unable to vote for the motion of Dr. Struthers.

Dr. Struthers briefly replied, and on the motion being put from the chair, it was carried by 19 against 4, five members not voting.

The Council then adjourned.

THURSDAY, February 17th.

Sir Thomas Acland, President, in the Chair.

The first item on the programme was a communication from Dr. McVail, during the consideration of which strangers were requested to withdraw.

It was moved by Mr. Marshall, seconded by Dr. Heron Watson, and agreed to:—

"That pursuant to Clause 4 of the Minutes of February 17, the following letter by Mr. McVail be now entered in the Minutes."

"General Medical Council Office,
"229 Oxford Street, London, W.,
"February 16, 1887.

"Dear Sir,—The point of order that I rose to speak to yesterday concerned the Commissions of the Representatives of the Scottish Universities, as read by the Registrar.

"These Commissions in all four instances are from the Senates of the Universities; in three of them this is formally expressed; and in the case of Glasgow, although not definitely stated in the document, yet the Senate alone made the appointment.

"I desired to call your attention to the circumstances, first, that the Medical Act of 1886 does not, in the case of any one of these Universities, restrict the power of election to the Senate; and, second, that the Scottish Universities' Act of 1858 is likewise without any such limiting provision.

"I hold that in the Scottish Universities the duty of electing the Representatives to the General Medical Council falls on the same constituencies that return the Representatives to the Imperial Parliament.

"I therefore regard the Returns read before the General Council yesterday as being quite invalid.

"I am, dear Sir,
"Yours faithfully,
"O. C. McVail.

"To Sir Henry W. Acland,
'President of the General Medical Council."

Conjoint Scheme in Ireland.

Mr. Collins moved:—

"That the Governor and Court of the Apothecaries' Hall of Ireland, having failed in their efforts to enter into a conjoint scheme of examination with the other Irish Corporations or Universities, respectfully request that the General Medical Council will be pleased to nominate an Examiner in Surgery for the Hall (the Governor and Court having been advised that to ask for one in Midwifery is not requisite), to entitle them to issue registrable qualifications, in accordance with Clause 5 of the Medical Act (1886)."

He appealed to the Council not to allow the Apothecaries' Company to be without a registrable qualification. It was, and always had been the wish of the company to combine, and he therefore asked for an examiner in surgery to be appointed under the Act of Parliament of 1886.

The motion was seconded by Rev. Dr. Haughton.

Some discussion took place on a remark by Sir William Gull, who said the request should come from the corporation and not from their representative but Mr. Collin's request was ruled to be in order.

Dr. Leishman criticised the wording of the motion, which he said was open to misconstruction.

Sir Walter Foster said he thought the resolution was premature on the part of the Apothecaries' Company, inasmuch as it was part and parcel of a great question which would have to be decided later on. The intention of the Act was to force combinations in each of the three divisions of the Kingdom so as to lessen the number of competing and rival licensing bodies. The Apothecaries' Hall was at present a medical qualifying body, and must be recognised as such. If the motion were passed, Mr. Collins would be the Bismarck of the situation and would be in a condition to initiate aggressive measures. He recommended Mr. Collins to withdraw his motion, the necessity for it not having been proved.

Mr. Collins then asked for permission to modify the wording of his motion so as to stand as follows:—"That in conformity with the request of the governor and court of the Apothecaries' Hall of Ireland of Nov. 9th already entered on the minutes of the present Medical Council, this council will proceed to appoint an examiner in surgery to issue registrable qualifications in conformity with Clause 5 of the Medical Act (1886)."

Dr. Struthers said it followed from their decision of the day before that the motion ought to be deferred so as to give time to the corporations of Dublin, to consider the resolution then passed. He proposed as an amendment "That the Council defer coming to a decision on the motion of Mr. Collins, in order to give the Royal College of Physicians and the Royal College of Surgeons of Ireland, and the Apothecaries' Hall of Ireland, time to consider the resolution passed by the Council yesterday on the motion of Dr. Struthers."

Mr. Teale seconded the amendment.

Dr. Matthews Duncan, the Rev. Dr. Haughton and others spoke on the question.

Dr. Glover asked whether an answer to their resolution of the day before might not be received from the colleges before the session was over? to which Dr. A. Smith replied that there was no possibility of such a thing.

Mr. Macnamara said the College of Surgeons of Ireland was most anxious to admit the Apothecaries' Society, and make a tri-partite arrangement. He was nevertheless opposed to the motion now before them.

Dr. Quain appealed to the members not to waste time in idle discussion. The question was a simple one. If the position of the Apothecaries' Society were menaced a special meeting of the Council would doubtless be called. The amendment was agreed to by the proposer and seconder of the motion, and carried unanimously as a substantive motion.

Mr. Thomas Laffan's Memorial to the Privy Council.

Mr. Marshall moved, and Dr. Banks seconded, that a communication from the Lord President of the Privy Council, enclosing a memorial addressed to the Lords of the Council by Mr. Laffan, of Cashel, with respect to the efficiency of qualifying examinations under the Medical Acts, and requesting the Medical Council to furnish their lordships with their observations on the memorial in question. With the memorial were enclosed extracts from the report of the visitors of the Medical Council on the examinations of the Royal University of Ireland, which the memorial said, would "show that the candidates for the degrees of the University are shamefully deficient in clinical training," and also "another document to prove that that University itself imposes restrictions which stand in the way of the adequate training of the said candidates, and that it has declined to remove the same."

Dr. Banks said he would not go into the charges, which alleged interested motives. He repudiated the idea, and explained that no slight had been intended to the union doctors, and the refusal to recognise the clinical training at infirmaries was based on the principle that no proper supervision could be exercised by the University authorities over the means or system of training. He proposed therefore, in reply to the request of the Lord President of the Privy Council, "That the Council, having before it the regulations of the Royal University of Ireland with respect to the attendance of students on hospitals, is of opinion that it is not expedient to take any action on the subject."

Dr. Kidd seconded the proposal, and said that the mere fact of their being union hospitals rendered them, from their very nature, quite inadequate for the due teaching of clinical medicine and surgery.

Rev. Dr. Haughton said that he did not think the letter came under the 19th section of the Medical Act (1886) at all, the clause in question implying something very much more serious. He disapproved of the spirit of the letter, but this fact should not be allowed to influence them in considering the important points raised as to whether they were or were not too narrow in limiting the field of hospital teaching by their regulations. He said the University authorities reserved to themselves the right to recognise this or that institution, according to the character of the teaching. He thought it would be well to agree to a resolution recognising, as a general principle, that, if the hospital teaching of any institution in the country, and the practice, were considered good, that it should be more or less recognised.

Sir Wm. Gull moved that this communication be referred to a committee to report, and then the Council could discuss it.

Mr. Simon, in seconding the motion, asked that the committee should sit to-morrow, and suggested that it should be an United Kingdom Committee. He said that although Mr. Laffan adduced a great number of instances of the ignorance of candidates he omitted to state whether they passed or not.

Mr. Pettigrew said that Mr. Laffan's allegation had no foundation in fact. Further, the date of the examination referred to was anterior to the passing of the Act.

Mr. Macnamara thought it ought to be made clear that no unworthy motives had actuated the medical gentlemen of the Royal University, and expressed his regret that such a charge should have been brought.

Dr. Banks said he entirely accepted the amendment, and would be glad to see the matter referred to a committee. They had been actuated solely by the consideration that workhouse hospitals did not provide materials for clinical study.

Dr. Kidd endorsed the remarks as to the unsuitability of these institutions for purposes of clinical study, and thought that constituted a complete justification of the refusal.

The amendment was then put to the Council, and carried as a substantive motion.

The Council and its Relation to Conjoint Examinations.

Dr. Heron Watson then moved:—

"That considering the somewhat anomalous position in which the General Medical Council is placed by the opinion given by Mr. Muir Mackenzie on the clauses of the Medical Act, referring to the qualifying examinations held by a combination of medical authorities, and the relation of the General Medical Council to such contracting bodies as may agree to hold qualifying examinations under such scheme, it is desirable that a further opinion from the responsible legal advisers of the Government be obtained before the Council proceeds to take any steps arising out of the interpretation of Sections XV, XVIII, and XIX of the Medical Act, 1858, construed along with Sections 1, 2, 3, 4, 5, and 6 of the Medical Act, 1886, together with the consideration of any other points which may arise within this reference, and that it be referred to the Executive Committee to take the requisite steps to give effect to this."

He said the position of the Council was very distressing as concerned their conduct towards those bodies which had been excluded from the conjoined schemes. He wished to be enlightened as to what the scope of their duties really was. He would propose that a committee be appointed to prepare a series of questions to be submitted to the legal advisers of the Privy Council.

Mr. Wheelhouse said he was not satisfied with Mr. Muir Mackenzie's opinion as to one Act superseding the other. It would be well, therefore, to take the highest legal opinion on the subject, especially after what had taken place yesterday. There was no particular hurry.

Mr. Simon pointed out that there was no such thing as an *authoritative* legal opinion.

An amendment was moved by Dr. A. Smith, and seconded by Sir Dyce Duckworth, "That the Council, instead of proceeding to vote on the question originally proposed, do pass to the next order of the day."

The amendment was not carried, and the motion was then agreed to.

It was moved by Sir Wm. Turner, seconded by Mr. Marshall, and agreed to: "That the Executive Committee refer the case [in the foregoing clause], when prepared, confidentially to each member of the Council for suggestions."

Report of Finance Committee.

Dr. Quain moved the adoption of the Report from the Finance Committee and its entry on the Minutes, and this was seconded by Dr. A. Smith.

Sir Wm. Turner called attention to the last paragraph of the Report, bearing on the question of dental finance. The fund had fallen from £9,824 in 1881 to £7,465 in 1887, and if this diminution were to continue, the vanishing point of the fund was within measurable distance. He asked whether matters were to be allowed to go on in this condition.

Dr. Quain said that no reduction was possible in the expenses, which had been agreed upon as one-sixth of the general expenses of the Council. The 5,000 dentists gave more work than the 25,000 medical practitioners. He suggested that a separate Board which would answer every purpose could do the work at one-tenth the cost.

Mr. Marshall said that the fees for registration of dentists were just then at a very low ebb, but that there was every reason to expect that these would shortly increase in number.

The motion was then agreed to.

On Dr. Quain's suggestion, Sir Walter Foster and Mr. Brudenell Carter were nominated members of the Pharmacopœia Committee.

It was moved by Mr. Marshall, and seconded by Mr. Simon, and agreed to, "That the printing of Mr. McVail's letter in the Minutes be suspended until after the Chairman of Business has made a further communication to the Council."

The Council then adjourned.

FRIDAY, February 18th.

Sir Thos. Acland, President, in the Chair.

Mr. Marshall said he had received most distinct and emphatic information that there had been no irregularity in the matters to which he had alluded last night when he proposed postponing the publication of Mr. McVail's letter. He asked the Council therefore to authorise the letter to be printed in the minutes. The motion was seconded by Dr. Heron Watson and agreed to.

Dr. McVail expressed his surprise that no opportunity of affording an explanation was afforded him before communicating with Mr. Marshall. On learning the nature of the information he had been at once able to show that it was founded on error. He regretted that such a course should have been adopted in a public matter.

The Financial Condition of the Council.

Dr. Humphry moved that a committee be appointed to consider the past and present income and expenditure of the Council and to report to the Council whether any, and if so, what, diminution can be made in the further expenditure of the Council. He said that his motion referred to the scale of fees to members. The expenses of the Council were very great and had caused dissatisfaction. The present system had been established by the old council, and might with propriety be revised by the new. In the Report of the Finance Committee read yesterday it was stated that constant vigilance would be necessary to secure that the annual expenditure should be within the limit of income. During the last seven years the excess of income over expenditure had been £1,400, but there was now an estimated increase of expenditure amounting to £1,200, and under these circumstances, the matter called for serious consideration.

Mr Wheelhouse seconded the motion, and said the committee would afford a guarantee that an eye was kept on the expenditure of the Council.

Dr. McVail wished the motion could be extended so as to provide for the Council to sit in London, Edinburgh, and Dublin in rotation. He said that a rearrangement of the fees was inevitable. He proposed that the fees should be abolished, at any rate for the members residing in the city where the Council sat.

Dr. Quain characterised Dr. McVail's proposition as preposterous.

Mr. Macnamara said the question had long interested him. He proposed that the motion should include the words "and also and in what manner the income may be increased." He said he had an idea how this might be carried out.

Mr. Simon thought a much more serious economy might be effected by a more strict organisation of the work to be done by the Council. He said the Council had certain definite statutory duties to perform, and these should be attended to, to the exclusion of "fancy" work.

Mr. Pettigrew thought Dr. Humphry's motion was inopportune.

The motion was then put to the Council, with the addition suggested by Mr. Simon, and agreed to.

The following gentlemen were nominated as members of the committee:—Dr. Quain, Dr. Dyce Duckworth, Mr. Marshall, Dr. Glover, Mr. Wheelhouse, Dr. Humphry, Sir William Turner, Dr. Bruce, Dr. Kidd, Rev. Dr. Haughton.

Mr. Muir Mackenzie, the solicitor to the Council, at the request of the President, stated that the questions which had been asked on Thursday as to the construction of the Act of Parliament was a difficult one, but he still adhered to his opinion. The only satisfactory way to settle the question was to get the opinion of some counsel of eminence in consultation or otherwise. There were no legal proceedings by which a decision could be obtained.

The President said that the Executive Committe would draw up a case and arrange the matter before the Council broke up.

Mr. Marshall moved:—

"That he will now furnish information in regard to the exceptional cases directed to be inquired into in Clause 7 (p. 27) of the Minutes of February 15, 1887."

He explained that the matter related to the exceptional cases returned by different medical authorities in reference to recommendations to Council which used to be known as No. 20: The cases at the Royal Colleges of Surgeons and Physicians were all graduates of Colonial, or Indian, or foreign universities, and had complied with the recommendation as to the length of the period of study.

A discussion took place as to the admission of students from foreign or Colonial universities who had not passed in Latin, and as to the exemptions from examination in such cases.

The Final Report of the Visitation of Examiners' Committee.

Mr. Marshall said he had endeavoured to make the Report as complete and as comprehensible as possible, and now it was all but finished. He thought the results of the visitation would be more useful in the form of conclusions than as recommendations, which might or might not be adopted. He therefore moved:—

"That the Final Report by the Visitation of Examinations Committee be received and entered as an appendix to this year's volume of the Minutes, and that separate copies be printed for publication."

The motion was seconded by Mr. Teale.

Rev. Dr. Haughton asked whether steps should not be taken to give effect to the remarks contained in the Report.

Mr. Macnamara referred to the remarks of the Visiting Committee as to the want of knowledge on the part of candidates in writing prescriptions in Latin, and asked whether this was to be given up.

Dr. Leishman said the strictures were perfectly correct, but he doubted whether such remarks properly fell within the province of the Visiting Committee at all. He said that the lack of knowledge on this point was as marked in university graduates as in the others.

Dr. Glover while bearing testimony to the efficiency and immensity of the labour done by the Committee, thought that the Council should see their way to endorsing the complaints, or the contrary. Considering that the visitation cost £2,500, he did not think they had the worth of their money if the Report were simply to be simply entered on the minutes. The criticisms on the want of clinical knowledge exhibited by candidates at the Royal University of Ireland had been sent down to the Privy Council, and it would appear as if the Council had evaded the expression of a decided opinion.

Dr. McVail said that the object of the visitation was clearly to enable the Council to know and to judge of the value of these examinations, although at the end of the Report it was stated that the object was "neither to admonish nor advise the universities, but to offer to those interested in the matter a connected view of the various methods, details, and opinions brought to light, &c." He said that this was a very platonic view of the duties of the Council, and if this were all they would better have left the money in the bank. He thought that several passages in the Report as to the unsatisfactory nature of the examinations in surgery, merited more careful consideration. He then proceeded to criticise that portion of the Report which stated that the candidates at the examination in surgery at Glasgow each performed two operations, and alleged that, from the number of bodies available, this was impossible.

Dr. Leishman protested against Dr. McVail's endeavour to impugn the veracity of the report.

The President thought Dr. McVail's remarks were irrelevant and requested him to confine himself to the point.

Dr. McVail, in continuation, said that it was not his intention to attack anybody, he merely criticised the figures.

The President requested Dr. McVail to write down his amendment if he wished to make one.

Dr. **Quain** protested against the reckless waste of time in discussing such matters.

Dr. **Matthews Duncan** entirely disapproved of Mr. Macnamara's and Dr. Glover's remarks. He said the Visitors had been invested with no authority whatever, and their reports would receive no sanction from the Council. Great improvements had taken place in consequence of the representations of the Council.

Dr, **Kidd** said that the instances of ignorance on the part of candidates had occurred with men who, for the most part, had already been up two or three times. The number of rejections at that examination had, moreover, been higher than usual.

Mr. Marshall's motion was then put to the Council and carried.

A vote of thanks to the Committee of Visitors was proposed and agreed to.

Moved by Mr. **Marshall** and seconded by Mr. **Simon**, that the report by the Sub-Committee on the Registration of Colonial and Foreign titles and Foreign degrees, adopted by the Executive Committee, be received and entered in the minutes.

This motion was carried.

REGISTRATION OF FOREIGN AND COLONIAL DEGREES.

Mr. **Marshall** moved, and Mr. **Simon** seconded, that the following new standing order, suggested by the solicitor, by direction of the Executive Committee be now adopted by the Council:—"That when an application is made under the provisions of Section 16 of the Medical Act, 1886, by a medical practitioner—already on the Medical Register by virtue of an English, Scotch, or Irish Qualification—to have the description of a Foreign Degree in Medicine possessed by him to be added to his name as an additional title in the Register, the Registrar shall require from the applicant satisfactory proof of the date of the grant of the said degree, and also such further information as may be necessary, in order that the General Council shall be satisfied before the title is registered, that the degree was obtained after 'proper examination.'"

Sir **Walter Foster** expressed the hope that none but good and sound foreign degrees would obtain access to the Register.

Dr. **Glover** asked whether the additions of foreign degrees to men already on the Register would be more extensive than that under the Foreign Registration Clause?

Mr. **Marshall** said that in any case it would be necessary for the applicant to show that he had passed a good and proper examination.

The motion was carried.

ERASURE FROM THE REGISTER.

The second Standing Order was then moved by Mr. **Marshall**, that:—

"Any application by a registered medical practitioner for removal of his name from the Medical Register shall, in the first instance, be referred by the Branch Registrar to the medical authorities who granted the applicant his qualification or qualifications, to ascertain whether there is any valid objection to such removal. The General Registrar shall bring such application before the next meeting of the General Council, who will consider the application and any objections thereto, and the President may put from the chair to the General Council the question Whether the Registrar shall erase the applicant's name from the Medical Register?

"The General Registrar shall, upon the removal of the applicant's name from the Register, send notice of such removal to the applicant by a letter addressed to his registered address."

Dr. **Struthers** suggested that it would be an easy way to get rid of the case simply by acceding to a request on the part of any practitioner to have his name erased.

Dr. **McVail** said that if the Council acceded to such a request, the person would be entitled to register afresh if he thought fit.

The motion was then put and carried.

COMMUNICATION FROM THE APOTHECARIES' SOCIETY OF LONDON.

It was moved by Mr. **Marshall**, and seconded by Mr. R. B. **Carter**, that a communication from the Apothecaries' Society of London together with the correspondence therein referred to be received and entered in the minutes.

The motion was agreed to.

SATURDAY, FEBRUARY 19TH.

It was moved by Mr. R. **Brudenell Carter**—

"That inasmuch as the master, wardens, and Society of the Art and Mystery of Apothecaries of the City of London, having used their best endeavours to enter into a combination with some other corporation or university for the purpose of holding a qualifying examination in accordance with the provisions of the Medical Act of 1886, and having reported to the Council that they have been unable to enter into any such combination, have in consequence, and in further compliance with the Medical Act aforesaid, made application to the Council for the appointment of Assistant Examiners accordingly."

He took up the history of the Society and claimed for it a large share in the present standard of medical education. He alluded to the large number of practitioners holding the license, many of whom had petitioned for the continuation of the Society. He said that the position of the English Apothecaries' Society was not quite on a par with that of the Irish company. He called attention to the fact that the movers and seconders of the amendments to be proposed were none of them resident in London, and might therefore be supposed to be less familiar with the needs of the situation. The examiners at the Hall were men of unexceptionable capacity and eminence, and their examinations fulfilled every requirement. He said he anticipated that his motion was a merely formal one, and would be agreed to as a matter of course, in which case he would ask them to nominate the gentlemen now holding the post of examiners in surgery. It would, he said, be an injustice to postpone the consideration of this matter seeing that if this were done the society might suffer in consequence.

Dr. **Chambers**, in seconding the motion, said that Mr. Carter only asked the Council to carry out a statutory duty which, if it were not done by the Council, would be done by the Privy Council.

Mr. **Mitchell Banks** and Dr. **Struthers**, both having amendments much of the same nature, it was agreed to merge them both in that of Dr. Struthers.

Dr. **Struthers** proposed, and Mr. **Teale** seconded the motion—

"That the Council being of opinion that it would be contrary to the interests of the public to have two competing Examining Boards sitting in London, and that it is desirable that the Royal College of Physicians of London, and the Royal College of Surgeons of England, and the Apothecaries' Society of London should arrange to hold a qualifying examination conjointly, strongly recommend to these medical authorities to reconsider their position with a view to such an arrangement; and meantime defer coming to a decision on the application from the Apothecaries' Society of London of 12th February."

Mr. **Mitchell Banks** thought that the action of the Council yesterday with respect to the Irish Apothecaries' Company, rendered it impossible to accede to Mr. Carter's request. He knew very little for or against the Apothecaries' Company of Ireland, but he was quite aware of the excellent work done by the English Society. Whatever one's personal feelings on the subject might be, it was their duty, in public as in private life, to do, now and again, disagreeable things. He could not see a single reason, except the memory of the past, why the Society should be galvanised once more into life. It was not a teaching but rather a trading body, and no harm would accrue from its ceasing to exist. The position of the Apothecaries' Society had been, for the last twenty years, the most inferior among English licensing bodies, and that could not inspire confidence for the future. He deprecated the establishment of an inferior class of practitioners, who would always grovel in their corner and never rise to anything better. The time when the apothecary was a doctor was gone, and the period during which the doctor will continue to be an apothecary was, he hoped, rapidly drawing to an end. As to the cry of injustice, if he had to choose between committing an injustice to a trading company, composed of a limited number of respectable elderly gentlemen, and running the risk of flooding the profession with a host of inferior men, he would take the former course. He did not believe the Privy Council woud be induced to act over their heads, and if they did, then the sooner the General Medical Council were abolished the better.

Mr. **Wheelhouse** said that a very general feeling existed in the profession in favour of the combination of the Apothecaries' Society. He would advise that the matter be referred to the Colleges with the expression that it was the desire of the profession that the combination should, if possible, be effected.

Sir **Dyce Duckworth** said the College of Physicians in London had never recognised the examinations of the Hall. By exclusion from the Conjoint Scheme, the Apothecaries' Society would be left in the position of an independent city trading company, whereas, if admitted it would amount to a voluntary extinction. He could not hold out any hope that the College would reconsider their decision. (Mr. Carter observed that the Society of Apothecaries had sought admission into the conjoined board, because they could not otherwise have applied to the Council.) In his opinion, the best thing for the Council to do would be to refuse to name examiners, and so provide for the extinction of the Society as an examining body.

Dr. **Struthers** thought the existence of competing bodies would be very objectionable, and have a downward tendency. The clause under which they were requested to act, provided not only for the appointment of examiners in surgery, but also in medicine and midwifery, in fact of a whole examining board. He urged that the very name of apothecary was undesirable. He would never willingly be a party to perpetuating the separate existence of the Hall by granting additional examiners, and if necessary would prefer to throw the responsibility on the Privy Council. If the College of Physicians had done its duty in 1815, the Apothecaries' Act would not have been passed, and the difficulty would not have arisen. He would point out to the Apothecaries' Society that they would have to prove that they had failed to combine "on reasonable terms."

Mr. **Carter** said that the College of Physicians had declined to admit the Society on *any* terms, reasonable or otherwise.

Sir **Walter Foster** said that as a direct representative he felt called upon to say something on this question. He should support the amendment, not from any hostile feeling to the Apothecaries' Society, but in the interests of all the parties concerned. This question lay athwart the great scheme of medical reform which he had worked at for years. He must protest against any step in the direction of creating a separate licensing body, but it was also his duty to raise his voice against the position taken up by the Royal Colleges. He deprecated any further class distinction in the profession of which there were already too many.

Rev. Dr. **Haughton** said the "one-portal" scheme was a lunatic idea. All people were not born with the same capacities, and he did not need to look beyond the Council to be sure of this. He saw no objection to the existence of the Hall as a separate body. He did not believe in monopolies.

Sir **Wm. Turner** said he thought the representation should be made to the colleges irrespective of what their answer was likely to be. The alternative suggested by Mr. Carter's motion could only be considered when every other means of bringing about a combination had been exhausted.

Dr. **Heron Watson** said there was no urgency in arriving at a decision with respect to the Apothecaries' Society. If their representation to the Colleges were unsuccessful they would then have to do their duty. He did not think they had acted kindly towards their sister institution and even if it were recognised to be decrepit, it was neither just nor generous to leave an aged relative exposed to the cold and inclement atmosphere.

Dr. **Glover** regretted that three hours should have been spent in discussing a question that should not have arisen. He would be no party to obliging the Apothecaries' Society to knock at the doors of the various bodies who had already refused.

Mr. **Marshall** said that in his position as the representative of the Royal College of Surgeons, he should abstain from voting. He thought that if it were represented to the College of Physicians that the admission of the Apothecaries' Society was for the public good, they might reconsider their decision.

Mr. **Brudenell Carter**, speaking on the amendment, alluded to the circumstances under which the provision allowing of appeal to the Privy Council was inserted. They had been assured at the time that it was in no wise the intention of the government to extinguish the Society but merely to force them into combination. Unless, therefore, he received an undertaking that a special meeting of the Council would take place before the Act came into force, it would be incumbent on the Society at once to petition the Privy Council to appoint examiners. The Society of Apothecaries had acquired a vested interest in medical education in this country which would not be put aside, and therefore the sooner they dismissed that idea the better.

The amendment was then put to the Council and carried by 24 votes to 4, six members abstaining.

Dr. **Heron Watson** moved, and Sir **Wm. Turner** seconded:—

"That, having received the final report of the Visitation of Examinations Committee, the Council determine that it resolve itself into a committee to consider Report of the Visitors appointed by the General Medical Council, together with the answers of the several Universities, in the light of that Report, and that it do so resolve itself into committee upon Tuesday next."

Dr. **Bruce** moved as an amendment, seconded by the Rev. Dr. **Haughton**:—

"That, in receiving the final report from the Visitation of Examinations Committee, the General Medical Council is happy to find that all the Universities do provide a sufficient guarantee that their graduates possess the requisite knowledge and skill for the efficient practice of their profession."

The amendment was put to the Council and carried, and the Council then adjourned.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 23, 1887.

THE GENERAL MEDICAL COUNCIL.

This Medical Parliament has again met for the discussion of matters bearing on professional education, &c. Once again the sanguine may venture to anticipate that some good thing may come out of Nazareth and may await the report of the proceedings with hope, if not with confidence. The President's address naturally dealt with the progress and history of medicine during the reign of her Majesty. He was enabled to point to very tangible advances in every branch of practice. Even if medicine has not progressed *pari passu* with the sister sciences, the same enthusiasm and scientific ardour which have done so much to help onward the allied sciences have not been altogether unproductive. Still more to the point was his sketch of the efforts for comprehensive medical legislation. Matters have vastly improved in this respect since the *fiasco* of 1815, but we are sorrowfully obliged to bear witness to the fact that much still remains to be done. It is not for us to apportion the responsibility for the present unsatisfactory condition of things, and we still hope that this age of progress will not leave medical education and the status of the profession entirely at the mercy of those who are directly interested in the continuance of the actual *régime*. The great question which has practically absorbed so far the time and energy of the Council has been the anomalous position of the Apothecaries' Societies in England and Ireland in view of the refusal on the part of the Colleges of Physicians and Surgeons in London and Dublin to admit them to take part in the conjoint examining boards. It is very fortunate that this important question should have come forward now that the Council has been to some extent reconstructed. It is only becoming, that the profession at large which is vitally interested in the subject should possess a voice through their elected representatives.

After much discussion, the Council resolved to do the only thing, probably, that they could reasonably be expected to do. They declined to accede to the demands of both Apothecaries' Societies to nominate examiners for the time being, and elected to make representations to the various bodies concerned, to the effect that they should reconsider their refusal. There are, however, very few reasons to suppose that their representations will be attended with the result they desire. There is every reason, indeed, to anticipate that the Colleges will maintain their refusal, and, on the other hand, the Society of Apothecaries in both countries have everything to gain by continuing to exist as separate and independent bodies under the auspices of the Council.

As was pointed out, the position of the Apothecaries' Society in England and that of the Apothecaries' Company in Ireland, are not altogether alike. So far as the English Society is concerned, at any rate, they have very good reasons for supposing that their extinction as a licensing body is not a likely contingency. Mr. Brudenell Carter, in his eloquent address on the motion to name examiners in surgery, spoke very plainly in this sense. He peremptorily informed the Council that the idea that the Council could, by refusing to appoint examiners, lead to the extinction of the Society as a licensing body was to be dismissed, and he menaced the Council with an immediate appeal to the Privy Council if his demand were not acceded to.

The Council shelved the question for the time being, but the time is very near now when they will be called upon to decide what course to adopt. It is urged on the one hand that the nomination of examiners in surgery is a statutory duty, failing combination, and that any failure to fulfil that duty would be remedied by the Privy Council. The Act, however, expressly allows the Council a discretion in the discharge of this function, and it would be a pungent reflection on the utility and power of that august body should their decision be stultified by the superior council. The position is a difficult one, and whatever course the Council decide upon is attended with embarrassment. In all probability, should their representations to the Colleges fail—as they are likely to fail—to modify the situation, the responsibility of naming examiners will be left to the Privy Council.

The Report of the "Visiting Committee," prepared at an expense of about £2,500, came up for consideration; and after all the trouble and expense to which these investigations have given rise, it was resolved simply to enter them on the Minutes. The strictures contained in this very carefully conceived report are to be left to produce what effect they may, on perusal, by the bodies whose examinations have been criticised, but no steps are taken either to endorse or qualify them. It is certainly the moment to wonder *si le jeu vaut la chandelle*.

The communication from the Privy Council in reference to Mr. Thomas Laffan's memorial on the lack of clinical knowledge possessed by candidates at the Royal University examinations met with a very unsympathetic reception, and was coldly bowed out. The result, discouraging as it may seem, is one which might have been anticipated without difficulty. The Council is not a congenial atmosphere for complaints against the powers that be, unless the power be a comparatively feeble body, such as a society of apothecaries.

The question of finance came prominently to the front. The expenditure of the Council, especially under the new Act of Parliament, is perilously near their income, and the prospect of a deficit naturally fills their minds with dismay. It seems certain that some reduction in the scale of fees is inevitable, though it can hardly be expected to be exactly popular. Mr. McVail, a rather revolutionary member of the Council, proposed that the Council should sit in rotation at London, Edinburgh, and Dublin, and suggested that the members resident in the town where the Council sat should forego their fees. Since he must have been perfectly aware of the impracticability of such an itinerary, his suggestion as to the fees must be considered to be a disingenuous attempt to dock the London members of their hardly-earned due. It is needless to say his proposals met with scant sympathy. Mr. Macnamara was provided with a scheme for increasing the income of the Council, and as he did not think proper to impart the nature of his idea, we shall await his views with curiosity and interest.

The new members of the Council have, as might have been expected, taken an active part in the proceedings, but their influence must not be over-rated. They have been eager in their denunciation of the flagrant waste of time which mars the efforts and increases the expense of the sittings of the Council, but beyond calling attention to the fact their protests are not likely to be effectual.

There can be no doubt that the present is a very critical moment in the evolution of medicine as a profession in this country. The obstacles are such as to test the business capacity of the Council to its utmost. If one could only be assured that matters were discussed with a view to their settlement instead of from a purely corporative and interested standpoint, much indulgence might be extended to their errors of judgment. Judging from the past, however, procrastination has been their most powerful argument. The peculiar constitution of the Council is largely responsible for their masterly inactivity, and we can only express our regret that the interests of the profession, are in the hands and to be dealt with by a body undefined and undecided as to its attributes, its duties, and its powers.

◆

THE INFLUENCE OF SMALL-POX HOSPITALS.

The solution of this question has been lately brought to a crisis by the weighty remarks of Dr. Buchanan, the medical adviser of the Government, in the recently issued Supplement to the Local Government Board's Fifteenth Annual Report. In that Supplement, Mr. W. H. Power's further researches concerning the influence of Fulham Hospital upon the neighbourhood around it are given *in extenso*, and Dr. Buchanan regards it as irresistibly proved that a Small-pox Hospital can spread the disease for the distance of a mile (at least) around it. We commend our readers to the perusal of Mr. Power's latest report on the subject, and to compare it with his previous ones; it will be plainly seen that for the third time in succession, and with successive improvements in administrative machinery, tending to reduce the chances of personal infection, as by ambulances, hospital officials, visitors and callers, to zero, the same uniform gradation of small-pox incidence is observed from circumference to centre of the mile area taken as the standard of investigation. Moreover, though no such precise inquiry has been made concerning the other four hospitals in London, yet the evidence of the health officers of the districts in which they are severally situated, based on the same method of analysis as that originated by Mr. Power, leads to the same conclusion concerning the institutions at Deptford, Stockwell, Homerton, and Hampstead. And, further, to show that this behaviour is not peculiar to the Asylum Board Hospitals, similar evidence is forthcoming concerning Highgate Hospital and some of the few hospitals that exist in the country. But, as Dr. Buchanan justly points out, the number of these provincial hospitals is inconsiderable compared to that which the metropolis contains; and hence the deduction, which is expressed by graphic statistical diagrams, that much of the unenviable pre-eminence of London in the matter of Small-pox has been due to the presence of such places in its midst.

The powerful indictment thus set forth is sought to be minimised by a short appended memorandum by Dr. Bridges, Inspector of the Poor-law Department at Whitehall, who for many years past has been entrusted with administrative supervision of the doings of the Asylums Board. In this document, Dr. Bridges accepts the facts as to the increased incidence around the hospitals, but poses as an apologist for them, relying on certain *ex parte* statements of the Registrar-General. He concerns himself mainly with disputing the mode in which infection has been distributed from Fulham, the particular hospital investigated, and cavils at certain minor *data* from which Mr. Power's exhaustive conclusions are drawn. For example, such matters as that the quarter-mile circle nearest the hospital escaped invasion at one time and was hit at another, and that the meteorological conditions of January, 1881, and May, 1884, though admittedly similar, were not precisely identical, are seriously put forward in answer to the broad generalisations arrived at by Mr. Power. Dr. Bridges' paper is, in fact, a mere *rechauffé* of stale objections which have been satisfactorily answered over and over again, and which can find favour only with those who are startled by the novelty of the new theory, so opposed to all their preconceived notions and the teaching of the schools, or with people who have not taken the trouble to master the subject from the first in all its bearings. His attitude is entirely negative, for while criticising, he fails to suggest.

For the Metropolitan Asylums Board, as a body in the main representative of the ratepayers of London, the question now becomes a serious one as to their future action with respect to the isolation of Small-pox. Since, in spite of the fact that the majority of cases during the 1884-5 epidemic were treated in extra urban hospitals, the greatly diminished numbers received into the intra-urban institutions still continued to spread the disease in their several districts, it is desirable either that some new policy should be instituted; or that the Royal Commission's recommendations as to the use of wards devised to burn their own infected air on the plan recommended by Burdon-Sanderson should be carried out without delay.

In the meantime, the Asylums Board is in a curious position, bandied about as it is, shuttlecock-fashion, between two Government Departments. It would be well if the Local Government Board could make up its mind to give advice firmly, decisively, and unanimously to that body. To this end, we cannot help thinking that it would be a distinct gain on all sides if in the future the Asylums Board were advised by the medical and scientific, rather than by the poor-law and administrative departments of the Imperial Government.

◆

THE APOTHECARIES' COMPANIES AND THE CONJOINT EXAMINATIONS.

We cannot but congratulate the Medical Council upon the solid sense they have shown in dealing with the exclusion of the Apothecaries' Companies of London and Dublin from the conjunctions of Colleges for the purpose of examination, and we most earnestly trust that the Colleges will emulate the business-like view of the subject which the Council has adopted, and will receive in good part the appeal made to them to shake hands with their old rivals and make them partners in the work which they have to do.

The case of the Irish Apothecaries came first under consideration upon the presentation of the Conjoint Examination Scheme of the Irish Colleges—of a challenge by the College of Physicians of the legal status of the Hall, a reply in vindication, and finally, a demand by the "Hall" for an assistant examiner to enable them to start the granting of independent diplomas forthwith. Very properly the General Medical Council unhesitatingly put aside the cases made *pro* and *con* on the question of legal status. We have already discussed this subject for the purpose of showing that, though the contention of the College of Physicians as to the legal incapacity of the "Hall" to grant medical licences under its charters was almost indisputable, the fact remained that the Act of 1858 and the subsequent proceedings of the Council had condoned that incapacity, and placed the "Hall" in as good a position to grant qualifications as the Irish College of Physicians itself, or any other licensing centre in the Kingdom.

Neither the statement of the College nor the replication by the "Hall" have in the least altered this opinion, and we say that the Council was wise in entirely disregarding a bygone controversy and proceeding to settle the question of to-day.

As to that settlement no second opinion is possible. It is clearly for the benefit of the public, of the medical profession, and of the Colleges and "Halls" themselves that their functions and forces should be joined in the erection of one strong and competent licensing centre for England and for Ireland. It was clearly the intention of the Medical Act of 1886 that this should be done, for it provided for the separate existence of any of these bodies only as an exceptional and inconvenient arrangement, and it was certainly the feeling of the Irish Colleges that there was nothing to prevent a coalition, for in 1875 they formally agreed to such an arrangement, and bound themselves to carry it out. We cannot be expected to assess the personal objections of individual Fellows of the Irish College of Physicians, nor to sympathise in any great degree with the aristocratic sentiment which prevents them recollecting we are living in the year 1887.

It is sufficient for us to know that there are no tangible hindrances to the admission of the Irish "Hall" to the conjoint examination scheme, while there exist obvious, numerous, and overwhelming objections to its erection into a separate licensing centre.

The General Medical Council, for these reasons, voted by 19 to 4 (six not voting) to send back the Irish Conjoint Scheme with a strong recommendation to the Colleges to instate the "Hall." That advice will be willingly adopted by the Irish College of Surgeons, and we repeat the earnest expression of the hope that the Fellows of the College of Physicians will withdraw their objection to the arrangement. They have, we think, sufficiently vindicated the dignity of their College by their public declaration that they repudiate the pretensions of the Hall to equality with them.

Surely they may now, in view of the objects to be promoted, concede something to the almost unanimous wish of the Medical Council and the undisputed opinion of the profession at large. We anticipate with confidence that their good sense will lead their decision towards a cordial *rapprochement* of all the Irish licensing corporations.

The Medical Council have applied to the London Colleges and the Apothecaries' Company exactly the same ruling as that made in the Irish case. They have by 20 votes to 4 strongly recommended the Colleges to admit the Hall to co-operation, and have, pending their decision, refused to provide the assistant examiners necessary to the "Hall's" separate existence.

Every appeal that we have made to the Irish College of Physicians we repeat with greater emphasis to the London Colleges. We feel of course that they are in a much stronger position than the Irish Colleges, but, on the other hand, the London "Hall" is in a much stronger position than its sister in Dublin, inasmuch as it has always been, beyond dispute, a medical licensing body and has done very large work in qualifying. It was for many years the sister of the College of Surgeons, and no cavil can be raised against its recognition as an ancient and highly respectable institution.

But Englishmen are, we think, much less likely than Irishmen to be swayed in matters of business by sentiment, and we are therefore sanguine that the consideration of rank and status will not avail to prevent an effective settlement, once for all, of long-disputed jealousies.

◆

Notes on Current Topics.

Evidence in Cases of Assault.

A gentleman residing at Lewisham, was charged before Mr. Montagu Williams, at the Greenwich Police Court last week, with assaulting a young woman in his employment as governess, by kissing her. The offence is not perhaps a serious one, but seeing that the defendant is alleged to have committed it after the plaintiff had gone to bed—"retired to rest," as she put it, it was certainly reprehensible. The defence was that the charge was "trumped up," but the magistrate, in the exercise of his discretion, fined him, and expressed his sense of the impropriety of the defendant's conduct. So far we cordially endorse his worship's remarks, but in view of the energetic repudiation on the part of the accused of any such indiscretion, we cannot refrain from calling attention to the extremely unsatisfactory nature of cases which are decided on a single, and perhaps unavoidably, unsupported testimony. It is not for us to question the wisdom or accuracy of the decision—against which the defendant has appealed—but the moment uncorroborated evidence by interested parties is accepted as conclusive, the door is opened to *chantage* of every description. No one suffers more from this procedure than the medical man, who is not unfrequently, alas! the victim of deliberate or delusive accusations of this kind. It may be urged, of course, that unless such evidence be admitted as proof of the offence conviction would be impossible. This would doubtless be the case, but there is a venerable maxim which says that it is better the guilty should escape than the innocent suffer. Further, if the victim of the assault felt aggrieved the best thing to do would be to leave, as promptly as may be, the inhospitable roof which had failed to shelter her. If the assault has not been carried beyond a kiss no great harm will have accrued, and anything of a graver nature would infallibly leave traces which could be adduced as circumstantial evidence of the transaction. Nobody is more anxious than we are to afford every possible protection to young women against insult or injury, but there are certain elementary rules which cannot be abrogated or held in abeyance without grave danger to society in the person of its members. The possibility of being charged and convicted on such grounds makes life in great centres an unavoidable peril for the best of men. Half the harm is done when the charge is made, and this quite irrespective of the result. We hope, rather than anticipate, now that the hysterical phase of excitement has passed, that some protection may be afforded to men, and that in future their sex shall not be considered *primâ facie* evidence of the offence.

Antiseptic Vandals.

If there be one antiseptic agent more than another which has made rapid strides into public favour, and this notwithstanding a penetrating and disagreeable odour, that agent is iodoform. For some occult reason, possibly connected with its chemical formula, it was elected to the freedom of the corporation of barber surgeons in all the countries of Europe. It has become an universal favourite in the treatment of everything, from a dog-bite to a chancre. This is the moment that certain individuals of ill-omen have selected to insinuate doubts as to its antiseptic powers. "'Twas ever thus from childhood's hour . . . I never loved a bird or flower, but 'twas the first to fade away." The poet, it is true, was not alluding to iodoform, but his plaintive language is very appropriate under the circumstances. The attack on iodoform is only part of a conspiracy against antiseptics in general. A gang—for they hardly deserve a better title—of scientific men, regardless of the alleged good effects which have followed their use, have undertaken to show that these good effects are in no wise attributable to the disinfectants and antiseptics on which we had relied to soothe our declining years. With the utmost disregard for our feelings, they openly laugh at the polished copper spray producer, and sneer at the admirable arrangement of our antiseptic dressings. They care nothing apparently for the *mise-en-scène* which their employment affords, and they cruelly insist that all is vanity. If their infamous designs be accomplished, it will only remain for us, metaphorically speaking, to hang our harp on the willow trees and weep the departed glories of antiseptic surgery.

The Resources of Journalism.

The *Pall Mall Gazette*, in its anxiety to maintain its reputation as a sensational journal, has thought fit to inaugurate a most objectionable form of "competition," an idiotic kind of *réclame* which has of late been much in vogue. They ask the opinion of their readers as to the best doctor "of all," the best woman's doctor and so on. Curiously enough none of the gentlemen to whom the *Pall Mall* have been the means of bringing an undesirable and perhaps unexpected publicity, figure on the list. If this sort of thing continue, it will scarcely be necessary to take a *plébiscite* of our readers in order to ascertain which is the most obnoxious journal.

Sanitary Assurance.

The annual meeting of the Sanitary Assurance Association was held on Monday, Sir Joseph Fayrer in the chair. From the report it appeared that the business of the Association during 1886 has been much greater than in any previous year, the income having been £804, as against £462 in 1885. Of all the properties inspected' in only two cases of first inspection had the arrangements been such that the Council could certify the sanitary condition of the property without alteration. Several meetings had been held for the purpose of revising the Sanitary Registration of Buildings Bill of 1886. In the new Bill the principle of compulsory registration would be restricted to schools, colleges, hospitals, asylums, hotels, and lodging houses.

Hospital Sunday Funds.

Not so much for the pecuniary value of the collection for the hospitals made in the various places of worship, is the amount contributed to medical charities valuable, but rather as an evidence of the respect and honour in which medicine as a profession is held by the people. It is gratifying to know that amongst all English-speaking peoples the medical charities are deemed worthy of support, and that a yearly contribution is so freely and generously given. Already the amounts collected in our principal centres of population have reached such proportions that the distribution necessitates an organised staff to properly carry out the work. The collection itself reacts healthily on the general public. The subscriber comes to feel a personal interest in the success of institutions for the welfare of which he has made sacrifices, and he naturally desires evidence of the success of the charities for which the collection was taken. In fact, a subscription when continued for some years assumes the character of a tax, and the broad and undeniable principle that there should be "no taxation without representation" comes to the front. That this question of representation is being seriously considered wherever the Fund exists is evident to all who give the matter serious thought. Recently it has occupied the mind of many subscribers to the Dublin Hospital Sunday Fund. Had there been a deputed representative from the Fund on the Whitworth Hospital Committee of Drumcondra, it is more than possible that the necessity for those grave complaints that have been made by letters and by leaders in the daily press, and the requests for withholding the annual grant would never have arisen. This latter is so serious a matter, that except in extreme cases we would be most unwilling to recommend its adoption, and we sincerely trust it may not be necessary with the hospital in question. Prevention is always better than cure, and a representative of the Hospital Sunday Fund on the Whitworth Committee would at least rescue that Hospital from the control of the family clique that is said to frustrate its usefulness and cripple its capacity for good work. Such a condition of things is more in conformity with mediæval times than the nineteenth century; and as the composition of the Committee is little in harmony with the age, the safer and quicker method would be for the Hospital Sunday Fund Committee to demand its reconstruction according to the original scheme of the Hospital's foundation—election by subscribers.

The Committee of the proposed "Victoria" Hospital at Bournemouth have received promises of subscriptions amounting to £2,800 towards the hospital which is to be erected on commemoration of the Queen's Jubilee. The Committee of the existing Cottage Hospital have £2,000 in hand towards the erection of a building which they have agreed to hand over to the Jubilee Committee, in order that there shall be one large and central institution.

The Lunacy Laws.

AN evening contemporary has very properly called attention to the danger to the public resulting from the natural reluctance of medical men, in the present state of the law, to sign certificates for the detention of persons supposed to be insane, which is once more illustrated by a letter from Dr. Forbes Winslow. It appears that Dr. Winslow gave his opinion, in reference to a case which was reported in the papers on Thursday, that serious harm would result if the person concerned were not locked up, but seven other medical men successively refused to sign a second certificate. It is no doubt a doctor's duty, as Dr. Winslow says, to act in these cases upon his honest opinion, and take the consequences. But this, says our contemporary, supposes a higher degree of public spirit than we have a right to look for in the average man, medical or non-medical. It is unfortunate that this should be the case, but until our legislators consent to afford medical men proper protection in the conscientious discharge of their duties, it is scarcely fair to tax them with a want of public spirit when they decline to run the risk of worry and ruin, in consigning to a suitable asylum, persons who, whatever their actual condition, may subsequently in a moment of comparative lucidity, make their medical man the unhappy object of their mania of persecution. The responsibility rests with the legislature which, as a general rule, thinks very much more of party than of public interests.

The late Professor Schroeder.

WE are able to add to what appeared last week a few particulars of interest regarding the death of this most eminent gynæcologist. About six years ago Professor Schroeder had the misfortune to get in the course of an operation some foul matter in the right eye. There followed acute inflammation of the eye, erysipelas of the face, and later pneumonia, the infective character of which was not, however, at the time suspected. After a protracted illness his health was restored, and he was sent to Cairo to recruit. From that time, however, he had been subject to attacks of giddiness and syncope, which were attributed to weakness of the heart. He was repeatedly urged by his colleagues whom he consulted to relax his labours, but it seemed impossible for the active, restless man rejoicing in work to do this. Last winter he was again attacked with serious illness, and he was sent to Nice. In November last year threatening symptoms again made their appearance, but he rallied, until fourteen days before his death symptoms of serious brain disease confined him to his bed. The symptoms were very complicated, and the friends who attended him, Professors Leyden, Gerhardt, von Bergmann, and Westphal could not decide as to the precise nature of the affection. The diagnosis lay between cerebral abscess, cerebral tumour, and meningitis, but no nearer decision could be reached. The prognosis, however, was the worst possible, and for some days before the mournful event took place all hope of his recovery was abandoned. He died on the 7th inst., leaving a widow and nine children, all of them young. The autopsy was conducted by Professor Virchow, and reported on by him before the Berlin Medical Society on the 9th inst. In the posterior part of the right cerebral hemisphere was an encapsuled abscess, about the size of a walnut. This had broken through towards the right ventricle, causing sharp hæmorrhage and acute inflammation. In the mediastinum also near the right lung and the œsophagus remains of a smaller abscess were found. No other trace of disease was discoverable. It is a sad reflection to have to make that the highest medical skill of the German imperial city was not able to save a valuable life that clearly could have been saved.

Libel Action against the "Lancet."

WE are happy to be enabled to congratulate our contemporary on the Platonic termination of the action for libel which Dr. Burnes thought fit to bring. By an oversight Dr. Burnes was asserted not to be on the official Register, an error which arose from a trifling misconception as to the manner in which he spelled his name. Naturally our contemporary hastened to make *amende honorable*, and there the matter should have ended.

Privileges of Licentiates.

WE recently noted a reply by the Editor of a medical contemporary to the effect that Licentiates of an Irish or Scotch Corporation were not entitled to dispense drugs in England, to which interpretation of the law we gave an unqualified contradiction, quoting the 31st section of the Medical Act, for the purpose of showing that every form of professional practice is open to every registered medical practitioner in any part of the Kingdom. The Secretary of the Edinburgh College of Surgeons has also addressed a letter to the same effect to the Editor, to which the following answer is now given:—

> "The answer in the *Journal* was intended to convey that, though a member of the Scotch or Irish medical corporation could, a member of a Scotch or Irish surgical corporation could not, without contravening the provisions of the Apothecaries' Act of 1815. To this answer we adhere, being informed that the Society of Apothecaries has no doubt on the subject, though when applied to (as it constantly has been) to allow prosecutions against persons who, registered only in respect of a surgical qualification, were practising as apothecaries, it has refused to do so."

With infinite respect for the interpretation of their own law by the Society of Apothecaries, we entertain no doubt that the Medical Act swept away any monopoly they possessed, *as against registered practitioners*. They still possess powers of prohibition and prosecution against unregistered persons, but, in the eye of the law, all registered practitioners are fully entitled to follow any or every branch of the profession in any part of the world over which the Medical Act has jurisdiction.

THERE recently died, at the age of 46, "the living skeleton," a man who for a long time served to illustrate the lectures on anatomy, delivered at Harvard, by Professor Holmes. The weight of the body did not exceed forty pounds, and during his life, the man directed that it should become the property of the College Museum on his death.

"Jacob Testimonial."

We are asked by the Honorary Secretaries and Treasurers of this Fund to inform gentlemen who have promised subscriptions that it is necessary to forward the amount promised to ensure their names being published in the address about to be presented. Any mistake in the lists published weekly will be corrected on the error being pointed out to the Honorary Secretaries.

The Penalty of Advertising.

It is satisfactory to note that some of our licensing bodies take a becoming view of of their duties and responsibilities. At the meeting on Saturday of the General Medical Council, communications were received from the Royal College of Surgeons in Ireland and the Queen's College of Physicians, announcing the withdrawal of the diplomas granted to William Edward Robson, of Estate House, Dundalk, and now residing at New Englefield, Staines, for having wilfully violated their regulations by publishing advertisements derogatory to the reputation, honour and dignity of the College—and, it might have been added, of the profession. If this course were consistently followed in all cases, a vast amount of good would be done, for persons so devoid of *esprit de corps* and self-respect as to advertise quack nostrums are not calculated to enhance the profession in public esteem.

Rare Case of Malformed Heart.

A case of congenital malformation, interesting from its rarity, is reported in a recent number of an American exchange. At the Colombian Maternity, Washington, a coloured woman in good health was delivered of a male child. At the moment of birth the child was cyanotic, and it was only after artificial respiration and stimulating applications vitality was restored. The baby lived fifty-four hours, during which time it had difficulty of breathing; very rapid pulse and action of the heart. The examination of the viscera had to be hurriedly made, and revealed the following: Lungs healthy, as was the abdominal viscera. The heart was found to possess only three cavities, two auricles and a ventricle. From this ventricle sprung the aorta, and immediately in front of the aorta at its origin was a small vessel three millimetres in diameter, that bifurcated eight millimetres from its origin. From the position, course, and bifurcation of this vessel, Dr. Lamb, of the Army Medical Museum, considered it was the pulmonary artery. The auricles were unequal in size, the left being the larger. The foramen of Botal was sufficiently large as to admit the tip of the little finger. In the position of the tricuspid valve there was a little ring of fibrous tissue, three millimetres in diameter. There was no opening, but a slight pouch-like depression seemed to mark the position of a rudimentary right ventricle. The left ventricle was normal, both in appearance and size, if in anything different from the normal, it was in a slight hypertrophy of the walls, which measured nine inches in thickness. Time did not allow of anything like a complete examination of the vessels, &c., a fact greatly to be regretted when we think how important a careful dissection of the pulmonary vessels would have been.

Medical Council Finance.

The Medical Council reports that in 1886 it received £9,741, and outlayed £8,991. It has earned £1,372 less than in 1885, but, on the other hand, has spent £3,092 less, so that it is £750 the richer of the year's operations. The increased expenditure is referable in some measure to the cost of the election of Direct Representatives, which cost, for England £483, for Scotland £204, and for Ireland £139—total £1,006. The apparent money-saving of the year is in the printing of the Pharmacopœia £2,150, and visitation of examinations £1,941. It is calculated that the enlargement of the Council by the addition of Direct Representatives will be £1,200 a year, and we do not doubt that they will be well worth the money. Already they have made their mark in the decisions arrived at by the Council.

The Diseased Meat Traffic in Dublin.

The disgusting trade in fevered carrion which the Board of Guardians in Dublin are driving has been brought last week into notice by the seizure of four pleuro-pneumonic bullocks which were in course of shipment to England. The guardians very properly destroyed these animals, but, as they would neither eat them themselves, nor insult the paupers in their workhouses by offering the meat to them, they sold them at about fourpence a pound to secret traders who acted as their agents to dispose of the diseased and poisonous carrion to butchers for the use of the purchasing classes. If this beastly trade were carried on by half-starved tradesmen it could be understood, but the astonishing part of the matter is that the guardians who lend themselves to this disreputable trade consider themselves highly respectable gentlemen, and they conduct their carrion market under the patronage of the inspectors appointed by Dublin Castle. In no part of Ireland is the selling of fever-poisoned meat prevalent except in Dublin, and in no part of the world would such trade be tolerated by the authorities except in Ireland.

Registration of Foreign Degrees.

The Medical Council has been constructing the standing orders under which it will register foreign and colonial degrees. The necessity for caution in this matter will be readily understood when the number of such degrees, some valuable and some absolutely fraudulent, which are granted under all circumstances, and in all parts of the world, is considered. Furthermore, the danger of affording undue facilities to idle and ignorant students to go abroad for a brief period and bring home registrable licences which their education would not enable them to obtain at home, must not be forgotten. The Council has very properly reserved to itself the right to debate whether the degree for which registration is solicited has or has not been granted after "proper examination." It is to be hoped that a recognition of a licence shall be in each case restricted to the recognition of the individual, and shall not cover a licence for all time. The means at the disposal of the Council to determine the merits of a particular examination are, in the great majority of cases, insufficiently precise to justify the Council to make a general recognition of their licences.

The Committee of the National Dental Hospital, Great Portland Street, London, inform us that it has been resolved to admit registered female medical students to the practice of the Hospital.

Lady Jessel has recently paid into the bankers of University College Hospital, London, a donation of £2,000 for the permanent endowment of a bed, to be called the "George Jessel" bed. The annual festival dinner of the charity will take place on April 27th, the Right Hon. Mr. Goschen, M.P., in the chair.

Dr. Laffan, of Cashel, has presented to the General Medical Council a very formidable indictment of the Royal Irish University, on the ground that its "candidates are shamefully deficient in clinical teaching," and that the "University imposes restrictions which stand in the way of adequate clinical training." He quotes the reports of the Visitors in confirmation of his charge, and his complaint is that the University does not accept certificates of clinical study from workhouse hospitals. this communication was addressed by Dr. Laffan to the Privy Council and sent on by them to the Medical Council, where it was referred to a committee for report. Time has not yet permitted of such report being made.

At the Societies.

PATHOLOGICAL SOCIETY.

At the last meeting of the Pathological Society of London a discussion, originating in a paper communicated by Dr. Hale White, arose, on the occurrence of loss of teeth in the subjects of locomotor ataxy, numerous references being made to recorded cases. The author did not, as yet, claim the dignity of a definite symptom of tabes for this occurrence, but he thought it desirable, in such a connection that many more instances in point should be carefully observed; and Dr. Semon mentioned that in tabes dorsalis loss of teeth was encountered under two sets of conditions. In one class the teeth fell out, painlessly, as described by Dr. White; in the other parts of the alveoli bearing with them quite healthy teeth came away, also without pain. Spontaneous and painless falling out of teeth had, he said recently been noticed in two of Dr. Ord's cases. Several other speakers having testified to similar experiences in their own practices, Mr. Bland Sutton drew attention to the fact that in carnivorous animals softening of the alveolus with consequent loss of teeth had been observed in association with softening of the cord and perforating ulcer of the foot. Sir James Paget commented on the highly interesting nature of the subject under discussion, and urged the solution of the problems involved through united efforts made by dentists and pathologists.

The next communication was one by Mr. D'Arcy Power, on specimens of inter-muscular synovial cysts exhibited by him, and it was discussed by Mr Godlee and Mr. Charters Symonds. Dr. Hyla Greves then showed an example of endothelioma of the dura mater, taken from a woman, æt. 60 whose health had been good up to fifteen months before her decease. Pain in the region of the right parietal bone then ensued, succeeded by epileptiform seizures, and ultimately left hemiplegia and double optic neuritis. *Post-mortem* the dura mater was found adherent over the affected part and to a greyish tumour composed of endothelial cells, containing "nests," which was deeply embedded near the fissue of Rolando. Dr. Carrington referred to a description of dura matral endothelioma given by Wilks and Moxon; and Mr. Eve mentioned a specimen presented by Mr. Goodhart to the Royal College of Surgeons, and which, on examination he was surprised to find was an angeiolithic sarcoma. Mr. J. Hutchinson, jr. urged that the term "psaminoma" should be dropped in favour of "calcifying endothelioma," and referred to a tumour of this description formerly reported by him. The growths in question differed, he said, from sarcomata in that they remained isolated.

On behalf of Dr. Jacob, of Leeds, Dr. Semon next exhibited photographs and microscopic specimens illustrating a case of hyperplastic syphilitic laryngitis in a child five months old, the subject of congenital syphilis, and on discussion arising on the communication, Dr. W. B. Hadden described an instance of aneurism of the mitral valve in a child, æt. 2½. Acute rheumatism and syphilis were both negatived in connection with the cases, the cause of death being bronchitis. There was a history of occasional blueness, but no cardiac murmur was detected during life. Both auricles and the left ventricle were dilated; the aneurismal sac was perforated, the edges being fringed by vegetations. Localised endocarditis was assigned as the cause of the aneurism, but whether originated during intra- or extra-uterine life no suggestion could be made. Dr. Coupland considered the case a remarkable one because of the primary origin of the affection in the mitral valve. Usually this became secondarily affected from the aortic.

Mr Shattock next showed a specimen of ectopia vesicæ, and propounded an anatomical explanation of the deformity which Sir James Paget characterised as ingenious and probable. Mr. H. Clutton then described a case of retro-pharyngeal abscess occurring in a man subject to epileptic fits. The abscess cavity communicated in front with the œsophagus by three round openings, and by one with the larynx. It also opened into the lung where the gangrenous pneumonia had been set up by the purulent discharge thus reaching the organ. Mr. Clutton was not able to offer any plausible explanation of the formation of the abscess, but Mr. Shield thought this might be found in the occurrence of hæmorrhage during an epileptic attack. In children he ascribed such abscesses to the influence of specific fevers, a theory rejected, however, by Dr. Angel Money on account of the extreme youth of many of the subjects of such abcessess. Dr. E. Clarke instanced a case in which careful search revealed a narrow sinus between the abscess and a curious cervical vertebra. The last communication of the evening was by Mr. Pearce Gould on a case of horny growth on the penis of a man, æt. 50.

MEDICAL SOCIETY OF LONDON—Monday, Feb. 21st.

Dr. E. Milner read a paper on the different modes of administering mercury in syphilis, and the indications for their application. The theme is not a new one, but the discussion shows that it is far from exhausted. Dr. Milner advises the use of the green iodide of mercury, with Donovan's solution and iodide of sodium in the treatment of syphilis in persons like barmaids, &c., who drink spirits freely. Inunction was, he said, especially indicated in the very early and the late stages of the disease in light-haired, abstemious persons, and finally, mercurial vapour in the local treatment of indurated sores or ulceration of the extremities. The course must extend over at least a year, and marriage should not take place under four years from the date of infection. Dr. Althaus spoke very highly of the tannate of mercury internally, and for inunction, of the oleate of mercury and blue ointment rubbed up with lanoline. Mr. Henry de Méric mentioned cases where, even at a late stage, mercury had relieved the symptoms when iodide of potassium had failed. There seemed to be a general opinion that while the iodides were very active in modifying or removing tertiary symptoms, they had no effect on the disease itself, which was liable to recur after some lapse of time.

It is surprising, after all the care and energy bestowed on the treatment and observation of syphilis, that such a wide divergence of opinion as to its effects and as to the influence of mercury in modifying its course should still be possible. Among men of great experience some pin their faith to the drug and others as enthusiastically oppose it.

Scotland.

[FROM OUR OWN CORRESPONDENTS.]

The Edinburgh Medico-Chirurgical Society.—A special meeting of this Society was held on Wednesday last for the purpose of carrying on the debate on "Empyema in its Medical and Surgical Aspects," adjourned at the previous meeting, and reported in these columns. A good deal of interest was manifested in the debate, and there was a large attendance of members. One Edinburgh correspondent has furnished a *resumé* of the proceedings, which will be found in another column under the head of "Transactions of Societies."

Accommodation for Lunatics in Scotland.—A memorial from the Magistrates and Commissioners of the burgh of Hillhead, Glasgow, relative to the proposed asylum at Hartwood Hill, has been forwarded to the Right Hon. A. J. Balfour, Secretary of State for Scotland. The memorialists explain the position of the ratepayers, the amount of the existing taxation, and the nature of the lunacy accommodation already provided. The proposed expenditure, the memorial goes on to say, will, if incurred, entail an unnecessary and double taxation for lunacy purposes on the ratepayers. They therefore crave:—1st, That the General Board of Commissioners in Lunacy for Scotland and the District Board of Glasgow be directed in the meantime to suspend building operations; and 2nd, That on being satisfied of the justice of the memorialists' claim, may move Government to introduce a bill dividing the said district of Glasgow according to the areas of management before mentioned, or restoring the power formerly existing to apply for and obtain such division or such other divisions as may appear just.

University of Edinburgh.—Purchase of Site for Union.—The Committee who are arranging for the Students' Union at the University of Edinburgh have at last acquired a most desirable site in close proximity to the Medical Buildings. It is the large stance presently occupied by Mr. Turpy's livery stables. The Committee have purchased it at a cost of £2,000. It is estimated that the buildings will cost about £10,000. Mr. Sydney Mitchell has been chosen as architect for the Union.

Scarlatina in Edinburgh.—The epidemic of scarlatina in Edinburgh continues serious. On Friday last there were 173 cases in the City Fever Hospital, 85 children and 88 adults. Only two cases have proved fatal in hospital. Two members of the profession have thought it necessary to appeal to the public through the medium of the daily press.

Dr. Johnstone McFie and the Glasgow Eye Infirmary.—The *affaire* McFie has created a good deal of talk in professional circles in Glasgow. We understand that the medical officers of this institution were appointed *ad vitam aut culpam*, yet in this case no *culpa* being hinted at, Dr. McFie is unceremoniously dropped at the annual meeting by simply not being re-elected. Dr. McFie is most fairly entitled to an explanation. Of course, at this institution all power and authority seem to be vested in the direct successors of McKenzie and Rainy, and it has been jealously guarded as their preserve, and the happy hunting ground for patients. We have recently had an example here of what looks uncommonly like palpable nepotism. We hope no such influence has been at work here.

Literary Notes and Gossip.

The List of the Fellows, Members and Licentiates of the Royal College of Physicians of London for 1887 is now obtainable. It contains nothing beyond the names, but these are arranged in several ways, so as to admit of ready reference, whatever may be the status of the person whose name is required.

⁂

France has lost, in the person of Prof. Béclard, a prominent official member of the medical profession, he having been for many years Dean of the Medical School of Paris. He has long been known as a writer of renown, his work on the heat phenomena attending muscular contraction having secured him a wide reputation in scientific circles. He was buried amid considerable ceremony on the 12th inst.

⁂

The French medical and scientific journals announce that a prize of fifty thousand francs is offered by the French Minister of Education for a discovery rendering electricity economically applicable in the shape of heat, light, chemical action, mechanical power, transmission of messages, or treatment of disease. A committee, with M. Bertrand, of the Academy of Sciences, as chairman, will adjudicate.

⁂

We understand that a work is well forward for the press by Dr. J. Milner Fothergill. Its subject matter is "vasorenal change *versus* Bright's disease," on which he contributed a letter to our columns some time ago. It will contain some advanced views it is said; and will attract a certain attention, though pathological topics have not figured largely in his extensive writings. Perhaps he is turning over a new leaf.

⁂

Dr. Dukes' works on School Hygiene, Moral and Physical, are well known and appreciated. The present, "Health at School," is a new and enlarged edition of his previous work on the subject. It comprises the consideration of the moral and physical training of lads prior to school life; on the choice of a school, and finally, on school life from its various aspects. For parents, schoolmasters, and others interested in schools, this volume will be found full of useful information, and the style is as commendable as the subject matter.

⁂

Dr. Buchanan's report to hand, "Report of the Medical Officer of the Local Government Board," which has been delayed, owing to the preparation of the Cholera Blue Book, is unusually interesting, since it contains important memoranda on the connection of scarlatina with disease in milch cows, on the influence of Metropolitan Small-pox Hospitals on the public health, as well as useful scientific reports on foot-and-mouth disease, tuberculosis, and the precise action of chemical disinfecting agents. We purpose to return to the volume at a later date, and to speak in more detail of the subjects of which it treats,

⁂

Nothing perhaps is more amusing than the involuntary errors of authors who, for reasons best known to themselves, have taken up a subject or the history of a subject with the details of which they are not familiar. Such a mishap—*inter alia*—has occurred in a history of medicine recently published, in which Eustachius is credited with having discovered a passage of communication between the middle ear and the *thoracic duct*. Such an error is calculated to make Eustachius turn in his grave. Matters touching medicine are peculiarly difficult to handle by unprofessional hands, and there was no need of this particular error to demonstrate the fact that the author was not a medical man.

⁂

GRAY'S ANATOMY, which it is presumed everyone who has "read up" for the profession during the past half century knows almost as well as his alphabet, has undergone a metamorphosis of a kind that will at once commend itself to students. In the new edition (the eleventh) to hand, Mr. Pick, of St. George's Hospital, the editor, has re-arranged and incorporated matter to such an extent as virtually to make it a new book; whilst the publishers have aided this praiseworthy change by printing the whole of the arteries, veins, and nerves in colours, instead of in ordinary white and black woodcuts, as in previous editions. Of course these alterations have necessitated an increase in price, but this will probably not be objected to in the face of such manifest improvements.

⁂

MANY of the diaries, the season for which is happily now past, think it necessary to state some event or another in connection with each day. The result is, that unless the compilers are archæologists as well as literary drudges, they are now and again run rather close for an incident for a particular date. Some of the less scrupulous of the community elude the difficulty by accommodating events to dates, much after the fashion that Scott is said to have done with historical facts. One can support the announcement of the death of Queen Anne, although the event is not now possessed of extreme political significance, but the death of Mr. So-and-So, Police magistrate in 1873 is more of an enigma. Perhaps the gentleman in question was a relative. It would be interesting to know what principles guide the editors of these diaries in their choice of events, and by what standard they guage their importance and utility.

⁂

TIME passes so rapidly that it seems but a few months since the death, in the prime of early manhood of Dr. Handsel Griffiths, the author of that very original and valuable *Text-Book of Materia Medica and Pharmacy*; yet two editions have appeared edited by other pens, and to the initiative of this author may be attributed many of the changes in the teaching of materia that have taken place of late years in our schools. The present edition of the work issued during the past few days, is edited by Mr. Alfred S. Gubb, gold medalist in materia medica at the Westminster Hospital. A hasty glance through its pages inclines us to pronounce on the thoroughness of his labours, he has brought the work into conformity with the new Pharmacopœia, has added a copious index, and has included in the section on Pharmacy a revision of Griffith's valuable "Notes on the Pharmacopœial Preparations." We hope to review the book more fully at a later date.

⁂

MUCH mischief may be occasioned by the publication of injudicious instructions to collectors of fungi, especially when care is not taken to be precise respecting the characteristics of those which are safe for human consumption. In this connection we commend for perusal the review of a work on British Fungi which has been written for *Nature* over the well-known initials "M. C. C." The book criticised professes to be an elementary text-book on the fungi of Great Britain, but the numerous errors and ignorance contained in it are freely exposed by the fungologist, who will be at once recognised by the initials in question. He most of all, however, protests, and very properly, against the mischief done by the author of the text-book in classifying under the head of "edible" fungi several poisonous species of mushroom, and concerning the results likely to follow from such a proceeding. "M. C. C." charitably hopes he may not be made conscious of his error in a coroner's court. We trust due warning may be given as to the dangerous tendencies of a guide so little calculated to lead to a due appreciation of scientific studies.

⁂

THE publication of the "Index Catalogue" of the library in the office of the Surgeon-General of the United States Army, at Washington, is steadily proceeding, the seventh volume of this magnificent work of reference being now available for use. This instalment of the Catalogue covers entries from "Insignares" to "Leghorn," inclusive, and contains 14,688 author titles, representing 5,987 volumes and 12,372 pamphlets, besides 6,371 subject titles of separate books and pamphlets, and 34,903 titles of articles in periodicals. The great labour on which Dr. Billings and his staff of assistants have been so long engaged is now about one half completed, the number of volumes which the Catalogue is expected to fill being fourteen. So far it is an enduring monument to the patience, learning, and skilful classification of the eminent physician entrusted with its compilation, and we earnestly wish for him long life and health, not only to finish his Herculean task, but also to enjoy the gratitude of those working members of the profession who find in this "Index Catalogue" such invaluable assistance in the prosecution of original observations.

⁂

IF evidence were needed to prove the value of publishing works on special subjects in a concise and practical form, the volume before us by Dr. Urban Pritchard, "Diseases of the Ear" (London: H. K. Lewis), would well supply the want. There is no doubt that the general practitioner requires more information on ear diseases than is to be found in most text-books on general surgery. He feels the want of directions how to diagnose many cases that come before him which will not yield to simply glycerine drops and haphazard inflation, and when diagnosed, how to remedy them. Yet, on the other hand, he does not want to wade through pages and pages of the history of the subject or vague theoretical reasonings. The happy medium has been most happily struck in Dr. Pritchard's work. We have conscientiously read the book, and do not hesitate to pronounce it to be one of the most concise and readable that we have hitherto met with on the subject. Specialists requiring an exhaustive work on otology must seek elsewhere; and yet the book contains everything necessary to students preparing for the higher surgical examinations. The value of the handbook is enhanced by the addition of an appendix of formulæ at the end. The illustrations, though not of the highest order, are clear and diagrammatic and serve considerably to elucidate the text.

⁂

NEW BOOKS AND NEW EDITIONS.—The following have been received for review since the publication of our last list, Jan. 26th.—The Science and Art of Obstetrics, by T. Parren, M.D., LL.D. Strümpell's Text-book of Medicine, translated by Drs. Vickery and Knapp. Zeisel's Pathology and Treatment of Syphilis, translated by H. Raphael, M.D. The Year-book of Treatment for 1886. Hip Diseases in Childhood, by G. A. Wright, F.R.C.S. Physical Diagnosis of Lung Diseases, by J. M. Finny, M.D. On Aphasia, by James Ross, M.D. The Bronchial Catarrh of Children, by J. Carmichael, M.D. Gray's Anatomy, Descriptive and Surgical, Eleventh Edition, revised by T. Pickering Pick, F.R.C.S. Animal Food in Health and Disease, by J. Berkett, M.D. Leçons sur les Malades du Système Nervous, par Professor Charcot. St. Bartholomew's Hospital Reports, vol. xxii. Diseases of the Ear, by A. Hartmann, M.D., translated by J. Erskine, M.A., M.B. Electricity in the Treatment of Disease, by J. R. Tunmer, M.R.C.S. Fifteenth Annual Report of the Local Government Board. The Asclepiad, vol. iv. Brain, Part xxxvi. Annual Report of the Crichton Royal Asylum. Proceedings of the Society for the Study of Inebriety. The Medical Annual for 1887, edited by Percy Wilde, M.D. Pulmonary Consumption, by Jas. Weaver, M.D. Medical Galvanism, by Herbert Tibbits, M.D. Atlas of Veneieal Diseases, by P. H. Maclaren, M.D., F.R.C.S.

◆

Olympia, Kensington.—Some 300 children of the Foundling Hospital attended the afternoon performance of the Hippodrome on Tuesday last, on the invitation of a lady patroness of the Hospital. A correspondent writes:—"It was a sight not soon to be forgotten to see them in their snowy white linen caps, tippets, and aprons, a costume well known to those who frequent the church attached to the Foundling Hospital. It was as though snow had fallen heavily on just one portion of the vast building. The children took the liveliest interest in the whole performance."

Correspondence.

THE BACILLUS FALLACY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Will you permit me to add as my mite to this controversy a quotation from Sir Charles Cameron's new work, "The History of the Royal College of Surgeons of Ireland"? On pages 19-20 Sir Charles refers to a Treatise on Consumption of the Lungs, "with a previous account of nutrition and the structure and use of the lungs," 8vo, pp. 276, published in 1727 by Sir Edward Barry, Bart., M.D., who states that under certain conditions consumption is contagious, but that unlike the acute fevers, its infective action is slow. He refers to a theory of the causation of the disease which is essentially the same as that lately advanced by Koch and others. Quoting from Martin's book on consumption, p. 57 *et seq.*, he says:—"Ulcers in the lungs, when narrowly viewed with microscopes, are covered with little insects, and thence concludes that they take their first origene from such *animalcules*, which, being inspired with the air, fix their situation on the lungs and erode and ulcerate their vessels." Barry rejects this hypothesis on the ground that the atmosphere teams with minute organisms which enter the body, but have no permanent abiding place therein, unless in disorganised structures incapable of resisting their attack. What were the "animalcules" seen by Martin? The above extract from Sir C. Cameron's "History" reminds us that not only what is true is not new, but also what is new (Koch's *deductions e.g.*) is not always true. The mere *presence* of a bacillus does not indicate tubercle, and, assuming that tubercle is the most favourable soil for the development of bacilli, we have yet to discover (perhaps *re*discover) what the favouring element in that soil really is. The "hereditary" (?) element in tubercular phthisis is the "receptivity" of the soil. In what does this "receptivity" consist?

I am, &c.,

London, Feb. 19th. Stop-Koch.

◆

ARTIFICIAL FECUNDATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—*A propos* of the above subject, to which you referred in your issue of the 2nd inst., it may be interesting to refer your readers to Sir Charles Cameron's recently published work on "The History of the Royal College of Surgeons in Ireland," on p. 7 of which appear the following lines:—"Dr. O'Connor, a native of Kerry, was physician to the celebrated John Zobieski, King of Poland. O'Connor received his medical education at Montpelier (then and long after a celebrated seat of medical learning). He proceeded to Paris, where he was admitted professionally to the Royal chambers, and thereupon added to his titles—*è Regiâ Cameræ Parisiensis Societate*. He passed the latter portion of his life in London, and died there in 1698, at the early age of thirty-two. He wrote the treatises, 'De Humane Hypogastri Saromatei,' 'Dissertationes Medico-Physicæ,' and 'Evangelium Medici.' In the last-named work he advances an opinion that generation may be effected without actual contact of the sexes, an opinion verified by recent experimental results."

Yours very truly,
A Fellow of the College.

◆

UNUSUAL SITE FOR HYDATID CYST.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—If Mr. Muskett will refer to pages 152-153 of Sir Astley Cooper's work on "Diseases of the Testis" (second edition, 1841), he will find the following:—"Of the animal hydatid in the testis:" "I have never seen this disease in the living subject, and therefore I know nothing of the symptoms which it produces. But Mr. Davie, who was formerly a dissector for our lectures at St. Thomas's Hospital, after one of the lectures, brought me a testis the epididymis of which contained a cyst, formed by adhesion; and within that cyst was an hydatid, having a pearly appearance, perfectly detached from the bag in which it was contained, and filled with a fluid of a watery appearance. The testis was somewhat larger than usual; but I do not think it was twice its natural size."

I am, &c.,

Holly House, Sunderland,
Feb. 16. James Murphy.

◆

INTRA-PERITONEAL HÆMATOCELE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—If Mr. Lawson Tait will look at the original report of my statement at the Pathological Society he will see that my contention is this—that pelvic effusions of blood in women are—firstly, divisible into two classes, perimetric or intra-peritoneal, to which the term hæmatocele should be and is very generally, confined; and parametric, or sub-peritoneal, to which the term hæmatoma should be, and is extensively, particularly in Germany, applied; secondly, that the majority of large and recognisable effusions are intra-peritoneal; and thirdly, that the large sub-peritoneal effusions, on which some abdominal operators have lately laid so much stress, are for the most part a new variety of disease due to a vessel in the broad ligament having been unintentionally injured or left insecure in an operation involving this part.

These matters can only be decided by careful and accurate observation, and if in any future discussion on this subject Mr. Lawson Tait will give detailed accounts of the seat of the effusion and of the consequent displacement of pelvic viscera as seen by him in cases in which he has opened the abdomen for blood or inflammatory effusions, a valuable addition will be made to the observations required.

I feel sure that Mr. Lawson Tait will also recognise the difference between misrepresentation, which is neither honourable nor useful, and criticism, which is often an aid to investigation.

This use of the term hæmatoma was suggested by Dr. Matthews Duncan, and is in accord with a mass of the best literature of the subject.

114 Harley Street, W., Yours faithfully,
February 19th. Walter S. A. Griffith.

◆

Medical News.

Royal University of Ireland.—The following additional Examiners in the Faculty of Medicine have been appointed for 1887.—Medicine: Stephen M'Swiney. Midwifery: John A. Byrne and H. M. Jones. Medical Jurisprudence: E. W. Davy and M. M'Hugh. Materia Medica: F. J. Quinlan and J. S. Read.

The Mortality of Foreign Cities.—The annual death-rates per 1,000 in the principal foreign cities, according to the last weekly returns communicated to the Registrar-General, are as follow:—Calcutta 29, Bombay 25, Madras 40, Paris 26, Brussels 22, Amsterdam 22, Rotterdam 23, The Hague 19, Copenhagen 25, Stockholm 22, Christiania 20, St. Petersburg 31, Berlin 23, Hamburg 28, Dresden 19, Breslau 29, Munich 26, Vienna 27, Prague 29, Buda-Pesth 34, Trieste 40, Rome 26, Venice 29, Cairo 40, Alexandria 30, New York 28, Brooklyn 21, Philadelphia 20, and Baltimore 18.

Cancer Hospital, Brompton.—The annual meeting of the governors of this charity was held at Brompton on Wednesday the 16th instant. Mr. Geo. T. Hertslet in the chair. The report of the committee showed that during the past year 1,628 new patients were received, 652 being in-patients and 976 out-patients. The total number of visits of new and old out-patients were 6,276, against 5,360 in 1885. This continued increase pointed to the necessity for increased funds, the reliable income of the charity being about £3,000 a year less than the ordinary expenditure, and an earnest appeal is made by the committee for continued support to enable them to carry on the important work of alleviating, and as far as possible arresting, the growth of this terrible disease. The medical staff give courses of lectures in the lecture room of the hospital during the first three months of the year which are open to all medical practitioners and students. The report and balance sheet were unanimously adopted, and the usual votes of thanks concluded the proceedings.

Notices to Correspondents, Short Letters, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attenion to this rule.

Reading Cases.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

Local Reports and News.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

James W. (Belfast).—Seeing that three millions have disappeared since the Black Forty-seven, while 706,000 of the four and a-half millions that remain are in receipt of pauper charity. and that this population is diminishing at the rate of one hundred thousand a year, we doubt the expediency of the Jubilee scheme you suggest. We think it, in short, impracticable at present.

Physician.—Sewill's "Student's Guide" contains enough for the general practitioner. Of larger and more exhaustive works, Tomes, Salter, or Stocken are the best.

Dr. Pearse (Plymouth).—The statement is somewhat vague; we have forwarded your letter to author, who is resident in the Riviera.

GYMNASTICS IN FEMALE COLLEGES.

A **recent** presidential decree in France, says *Science*. regulates the nstruction in gymnastics in the *lycées* and colleges for girls. The instruction must be given by female teachers, who must have received a certificate of aptitude from the proper authorities. Such teachers are to receive from 1,200 to 2,000 francs per year each (about £48 to £80), and may be required to teach sixteen hours a week. They must teach at least twelve hours a week.

A Puzzled Student.—Hardly a fair question to set. Myrobalanus is from the Greek μύρον "ointment" and βάλανος an "acorn," or any similar fruit. The myrobalans (a dried Indian fruit) are said to have laxative as well as astringent qualities. They are almost unknown in medicine in this country.

W. B. G. (Bristol).—The application was certainly a reasonable one, and deserved more courteous treatment. We would advise you to write to the Local Government Board, stating briefly and plainly your case, and doubtless an investigation will be the result.

THE CAUSES OF WARS.

A **well-known** French statistician has analysed these, and arrives at the following conclusions anent them:—He limits his inquiries to the last four centuries, and examines two hundred and eighty-six wars in all. Of these fifty-five were civil wars; forty-four were wars of conquest and land robbery; forty-one were wars of succession, or of crown claims; thirty were, as M. Leroy-Beaulieu puts it, wars under pretence of helping allies; twenty-eight were professedly religious wars, but most of these were waged on an old monarchical principle, *Cujus regio, illius religio*; twenty-four were wars of retaliation; twenty-two were wars for taxes; twenty-two were wars of commercial rivalry; eight were wars on so-called points of honour or prerogative. Amongst the wickedly capricious causes of the wars of the French monarchs of the seventeenth and eighteenth centuries, we find such entries as "A war for a window," and "A war for a glove."

Kensingtonian.—We have given all the information in our possession about the proposed Jubilee Hospital at the West End. The rumour which you have heard that it is being promoted principally by Jews may or may not be correct. We understand that two members of the medical staff belong to that persuasion. We further understand that some of its supporters are making a house-to-house canvass on its behalf near Earl's Court and West Kensington.

Evan Jones.—The subject is occupying our serious consideration. We hope to deal with it shortly.

Dr. M. (Sheffield).—In type, awaiting space. The proceedings of the Medical Council have crowded out a good deal of other matter.

Neurologist.—True, indeed, such things do at times occur, and as to the phantasms you describe, would not this meet the requirements of your theory? Keats is, we believe, the writer of it:

> . . . . things unreal and phantoms vain
> Which morbid minds spew forth as fumes
> That circling rise and take on lying forms.

A Puzzled Inquirer.—'Tis so, and the gall bladder and the fat of the python are much sought after by the natives of Burma. The former is in high esteem for its medicinal virtues, and as to the latter, the fat is used as an ointment for the cure of rheumatism, strains, and other similar inflictions.

Naval Surgeon.—You are quite right, and the jelly-like matter found in the nests of the commom swift, as well as, or rather chiefly in that of his smaller congener, the Chinese swiftlet, is nothing more nor less than "inspissated mucus from the salivary glands" of these birds. Unable as they are to perch on the ground by reason of the shortness of their legs, they either seize upon a nest already used, or they pick up such materials on the wing, such as feathers, thistledown, &c., as come next to hand. These materials they cement together with their copious mucus, for which purpose their salivary glands are peculiarly developed. As the spider, in short, spins its web out of its own body, so the swift finds it cheaper in the end to build a nest out of its own secretions, and hence the pure mucus which your Celestial neighbours are so fond of. We advise you not to touch it.

A Governor (London).—Letter unavoidably held over, it shall appear in our next.

◆

Meetings of the Societies.

Wednesday, February 23rd

Hunterian Society.—At 8 p.m., Dr. Scarth: A Review of Forty Cases of Diphtheria, illustrating its Manner of Spreading, and its Relations to other Fevers, to Diathesis, and to Neurotic and Paralytic Conditions.

British Gynæcological Society.—At 8.30 p.m., Specimens will be shown. Adjourned Discussion on Dr. Fitzgerald's paper on the Use and Abuse of Pessaries. Council at 8 p.m.

Neurological Society of London.—At 8.30 p.m., Exhibition of Clinical Cases.

Friday, February 25th.

Clinical Society of London.—At 8.30 p.m., Dr. Hughlings Jackson: A Case of Paralysis of Left Leg from Subcortical Disease. Dr. Carrington: A Case of Rheumatic Hyperpyrexia treated by the Cold Bath. Dr. Hadden: A Case of Epilepsy following an Injury to the Leg. Mr. Bowlby: Cases of Profuse Hæmaturia in connection with Granular Kidney. Living Specimens: Dr. Arthur Davies: Two Cases of Myxœdema (male and female).

Saturday, February 26th.

Royal Institution of Great Britain.—At 3 p.m., The Righ Hon. Lord Rayleigh: Sound.

Vacancies.

Salford and Pendleton Royal Hospital.—District Surgeon. Salary £80 per annum, with board and lodging. Diplomas and testimonials must be sent to the hospital on or before Monday, the 28th inst.

West Herts Infirmary, Hemel Hempstead.—House-surgeon and Dispenser, who shall also be Assistant Secretary. Salary £100 per annum, with board, furnished rooms, fire, lights, and attendance. Any further information can be obtained from the Assistant Secretary.

Preston and County of Lancaster Royal Infirmary.—Senior House Surgeon. Salary at the rate of £100 per annum, with lodging, washing, and board, exclusive of wine, spirits, and malt liquors. Applications with testimonials must be sent free on or before the 28th inst., addressed to the Secretary.

Dumfries and Galloway Royal Infirmary.—Assistant House-surgeon. Board and washing. No salary. Applications to be sent to the Treasurer before the 28th inst.

Appointments

Clarke, F. H., M.B., C.M.Ed., House-Surgeon to the Great Yarmouth Hospital.

Fitzgerald, G. C., B.A., M.B., B.C.Camb.. M.R.C.S., Junior Assistant Medical Officer to Cane Hill Asylum, Surrey.

Hinshelwood J., M.A., M.B., C.M., House-Surgeon to the North Riding Infirmary, Middlesbrough-on-Tees.

O'Brien, P. M., M.R.C.S, Resident Medical Officer to the North London Hospital for Consumption, Hampstead.

Skelding, H., M.B., B.A.Camb., M.R.C.S., Resident Surgeon to the Bedford General Infirmary.

Stacy, J. H., L.R.C.P., L.R.C.S.Ed., Medical Officer to the First District of the Henstead Union, Norfolk; also Medical Officer to the Sixth District of the Norwich Union.

Symes, G. D., M.R.C.S., Assistant Medical Officer to the Lancashire County Asylum, Rainhill.

Waldo, F. J., M.A., M.D.Cantab., M.R.C.S., Assistant Physician to the Chelsea Hospital for Women.

Wheatly, A. W., M.B., S. Sc.C.Dur., M.R.C.S., Surgical Registrar and Anæsthetist to the National Orthopædic Hospital.

Births.

Farr.—Feb. 16, at St. Heliers, Ealing, the wife of Earnest Farr, M.R.C.S., of a son.

Gardner.—Feb. 19th, at Clifton, the widow of E. Barton Gardner, Surgeon-Major, M.D., of a daughter.

Marriages.

Craig—Snoad.—Feb. 16th, at Knighton Parish Church, Leicester, Jas. Craig, M.B. Ch.M., to Amy, daughter of E. H. Snoad, M.R.C.S., of Aylestone.

Duckworth—Smith.—Feb. 16, at Donaghmore, Richard Henry D'Olier, M.B., L.R.C.S.I., to Florence Henrietta Josephine, youngest daughter of the late Henry J. Smith, F.R.C.S.I., of Rallybrophy, Queen's County.

James—Driffield.—Feb. 17th, at Prescot Parish Church, David James, M.D.Ed., of Ashton, to Letitia, daughter of the late W. W. Driffield, of Liverpool.

Deaths.

Braddon.—On Feb. 5th, suddenly, at his residence, Ham House, Upton-on-Severn, Charles Braddon, M.R.C.S., aged 71.

Edwards.—On Feb. 19th, suddenly, at 493 King's Road, Chelsea, Mary Amelia, wife of C. A. Edwards, L.R.C.P., L.R.C.S.Ed.

Prentis.—On Feb. 14th, at Calcutta (on his way to England), Surgeon-Major Chas. Prentis, Bengal Medical Service, M.R.C.S.; aged 51.

Rider.—On Feb. 10th, John Rider, of Wellington, Shropshire, M.R.C.S., L.S.A., aged 64.

Ritchie.—On Feb. 15th, suddenly, at Liverpool, Mr. Barry Ritchie M.D., J.P., of Belfast, aged 70.

Clinical Lecture

ON

THE TREATMENT OF TYPHOID FEVER. (*a*)

By Professor H. NOTHNAGEL.

Vienna.

WHEN in relation to the treatment of typhoid fever, we keep in view the plan we always follow as regards treatment, and lay before ourselves the questions of the indications: 1. The *indicatio causalis.* 2. The *indicatio morbi.* 3. The *indicatio symptomatica,* we must say to ourselves that as regards the first there is nothing to be said. The *indicatio morbi* would consist in having a remedy able to destroy the bacillus of typhoid without destroying the individual.

I take a decided stand as regards the treatment of the acute infective diseases upon the point that we must search for such so-called specific remedies. In quinine we have had such a specific remedy for malaria for the last two hundred years. We know that quinine renders malaria poison innocuous, without damaging the organism, and if syphilis, as it really seems to do, depends on an infection by bacilli, we know that mercury and iodine gradually destroy the syphilis bacilli without the organism being destroyed or damaged. The task of therapeutics, as regards the acute infective disease, is in general to search for specific remedies; that would be a real treatment of the disease, everything else that we employ, kairin, antipyrin, quinine, tartarised antimony, &c., is only symptomatic treatment. Have we any remedies that act specifically or not? No. Iodide of potassium has been recommended, as it has been recommended for pneumonia. Long ago I tried iodide of potassium for typhoid without any success. In parenthesis, I will also remark here, that I have tried iodide of potassium in croupous pneumonia up to 14 grms. in 24 hours without any injurious effects. Then I mention that it was stated recently by Ehrlich that thallin exercised a certain specific action upon typhoid. You know that Dr. v. Jaksch first recommended thallin as a remedy that reduced high temperatures, and it is one that has borne out the claims made for it, in a remarkable manner.

According to the observations we have made here in the Klinik, however, in typhoid it has not appeared to us that thallin does exercise any specific action upon typhoid. Ehrlich expresses himself cautiously and reservedly, he has stated that it appears that thallin exercises a specific action upon the typhoid process; according to the observations that we have instituted in our Klinik it is decisive that we succeed in keeping patients apyretic by methodical and continuous treatment by thallin, the disease has run its course in all the cases almost without fever, but notwithstanding this it lasts longer than it usually does without; we have seen nothing of any specific action that must declare itself by a cutting short of the process; as soon as we left off the thallin, the temperature quickly mounted up and the symptoms of the disease became more pronounced. Of all the remedies that have been recommended for typhoid, not one has stood the test, not even calomel, which was recommended to shorten the disease, to render it abortive as it were. Calomel was first recommended towards the end of the forties by Thierfelder and Wunderlich and frequently afterwards, the last communication on the abortive action of calomel on typhoid have come from Weil who was then in Heidelberg, but is now in Dorpat. On the whole, I agree with the opinions of Weil. If calomel is given as an abortifacient in typhoid it is the rule that it should be given in the first week when the diagnosis of typhoid is first probable. In this way a milder course, not a cure, but a shortening of the disease, is obtained; I have not been able to convince myself that it is so really. I believe that we are liable to great deceptions when we have no statistics of observations that extend over hundreds of cases; the objection is always possible that the case was one that ran a shorter course spontaneously. Calomel may be looked upon as acting in two ways, first as a purgative that removes the bacilli from the intestinal canal, and that thus removes a mass of material that would otherwise be taken up into the circulation. If this conception is correct that which is obtained with calomel will also be obtained by means of other purgatives that can be given in diseases of the intestinal tract, for example with ol. ricini. I have in fact, after comparative investigations gained the impression that castor oil acts exactly like calomel. Those observers who plead for the abortive action of calomel have also pronounced the following opinions:—You are aware that, according to the investigations of Koch, sublimate is the most powerful parasiticide. Calomel on being retained in the intestine becomes converted into sublimate and in this way, it is claimed, the bacilli in the intestines are destroyed. But this has not been proved, and we come to the result of our observations made hitherto, that we do not possess a specific for typhoid fever.

Symptomatic treatment is then the only one remaining, and what we are able to perform in the treatment of typhoid is done by means of symptomatic treatment. We must now be quite clear what indications we have as regards symptomatic treatment. These as regards typhoid may be extraordinarily numerous. If intestinal bleeding takes place the indication arises to treat the hæmorrhage, or if decubitus takes place, or a serious affection of the lungs, we must treat these, in short, the indications are extraordinarily varied in accordance with the complications. I will, however, at present refrain from entering upon the treatment of all these complications for their treatment is the same in typhoid as when these symptoms appear independently. If you have intestinal hæmorrhage to treat from an ulcer in typhoid, or in consequence of carcinoma, or as a result of an embolism of the *anteria mesaraica,* &c., in all these cases the hæmorrhage is treated in the same way; and the same with the treatment of hypostasis of the lungs and atelectasis in the course of typhoid as when these symptoms come on in the course of whooping-cough, measles, or in an old man in the course of a bronchial catarrh, the treatment in all these cases is the same.

(*a*) A Clinical Lecture delivered in the Medical Klinik of the University of Vienna, January, 1887.

What I shall describe here are the indications that an uncomplicated case of typhoid presents. What is our task here? The organism itself is in a position to overcome the typhoid poison, whether it be that the cells of the organism eat up and so destroy the bacilli of the disease, whether it be that the bacilli destroy themselves by means of the secretions which they afford, and thus it matters not what the process may be; we see eventfully that the bacilli come to nought and the man is restored to health. We see on the other hand, however, that a typhoid patient becomes much exhausted, much emaciated on account of insufficient ingestion of nourishment, the patients eat insufficiently, they have no appetite and when they are sensible they generally desire nothing. Secondly patients emaciate on account of the direct loss that the fever brings with it. You know that in fever increased metamorphosis of tissue takes place, more urea and more carbonic acid are excreted, the acid products of tissue change are produced in richer quantity, first the albumen circulating with the nutriment is taken, then the organic albumen is used up, then the carbo-hydrates, the fats, in the body are attacked, in short, the man emaciates, he becomes exhausted in consequence of the fever. Thirdly, we see that emaciation can be brought about by mere accidental things, for example copious diarrhœa, if the intestinal contents which would be otherwise resorbed, do not become so in consequence of the diarrhœa.

There are thus various factors that can reduce the system during typhoid fever. It is an indication of the first rank in typhoid to enable the system to hold out. Food must be given, the fever reduced and the abnormal secretions kept within bounds. These are the three indications that meet us in every case of typhoid, even in the uncomplicated ones. You understand that we are less compelled to answer these indications in the milder cases, that run their course in ten or twelve days, when at the same time the fever is not so high, &c. The first thing we have to aim at then is to feed the patient. I, as well as a number of other clinicists, have completely broken with the old tradition of putting fever patients upon a so-called bland diet; for a number of years past I have taken my stand upon the point that we must feed such patients energetically, and I would put it to you as the first and most urgent indication to feed such cases well. It is self evident that you should not give them roast pork, mutton cutlets, vegetables, cabbages, or great lumps of potatoes, &c., for you will not forget that the patients are suffering from fever, and that in typhoid the digestive powers are reduced; above all you should not forget that they have a serious intestinal lesion, ulcers of the bowels. We must then give our patients food, but in the form that is most easily digestible, and thus in the fluid form.

(*To be concluded in our next.*)

Original Communications.

ON THE MANAGEMENT AND SELF-MANAGEMENT OF GOUT, OR THE URIC ACID DIATHESIS, AND "THE GOUTY."

By J. MORTIMER GRANVILLE, M.D.

(*Concluded from page* 168.)

It is clearly conducive to the solvent power of the fluid and helps to maintain the natural heat of the body to take as much as may be of the water consumed with this purpose warm. And here I must be allowed to make a statement based on observation and experience which, however opposed it may seem to the views propounded by some excellent authorities, appears to me to be of very great importance. It is that tea not too strong, made with what is called "black" tea, the water being only just boiled so that it has not lost its capacity for taking up extractives, and not being allowed to stand too long on the tea leaves, lest the residual extractive should be taken up, is a most admirable stimulant to the kidney function and supplies precisely the sort of drink which the gouty require. I have never seen a great tea drinker who suffered badly from gout. There may be such persons, but I do not chance to have met one. It is inexplicable to me that "the faculty" should condemn tea. I have drank on the average three or four pints daily of fairly strong tea for the last forty years or more, and in spite of a strong tendency to gout, I have succeeded in keeping it in abeyance, and am not conscious of any ailment for which tea can by any stretch of ingenuity be held responsible. Confessedly we councillors of the unhealthy are apt to shape our advice too much in accordance with our own particular likes and dislikes and personal experiences, so that it may well be that I am too warm in my eulogium of tea, but I must protest that the vigorous opponents of tea drinking are even more open to reproach because the evidence they have to produce in support of their arguments is at the most purely negative. Let the gouty, then, if it please them, drink plentifully of not over-strong tea. There is no reason in the world why they should not take sugar in it, and milk is admitted by all to be beneficial, so that by the combined leave of those who agree with, and those who differ from, me, the patient be he ever so gouty may enjoy his tea in peace, and withal if he will only give his mind to it, do much to relieve himself of the gout by its use. For those who dislike tea, as it is the fashion to drink it in this country, there is the Russian method, lemon juice being added to the infusion of tea leaves instead of milk and sugar. The tea will stand for a nearly, but not quite, equal quantity of water in the process of kidney flushing. Any other bland fluid may be substituted, but allowance must be made for the depreciation of the solvent power of pure water by the increased specific gravity due to the matters dissolved in the beverage.

I have of late used distilled water—saturated with hydrogen gas (to about 2 per cent. by measure) and slightly iodised,—with advantage as a solvent or diluent drink. Not less than four pints of water, either holding proportionally very small solids or pure, is to be consumed in the twenty-four hours; precautions being taken by measuring both the fluids consumed and the urine passed, and by testing the latter to make sure that the water thus taken is properly eliminated, and so it answers the purpose of carrying off the uric acid or urates which it is required to eliminate. This last point can readily be determined by estimating the uric acid and the urea quantitatively. Haycraft's uric acid test and the hypobromite test for urea are so facile that no difficulty will be encountered in having the proper examination made at suitable intervals, and no gouty person who desires to be well should allow the facts, as to the manner in which his organism performs its functions to be ignored. It is on the due performance of these functions that health depends, and, as a rule, long before any symptoms of gout declare themselves there are warning signs of defective eliminations which it is all important to recognise. A rough and ready mode of ascertaining that matters are not far wrong, well within the reach of the gouty person himself, would be to make sure that, while the total quantity of fluid eliminated in twenty-four hours is not less than three-and-a-half or four pints in summer when much fluid is unavoidably lost by the skin, and five or six pints in winter, the mean specific gravity does not fall lower than 1015. If the density of the fluid be higher than 1015, while the quantity is large there must be an excess of solids and more fluid is requisite, for the preventive treatment of gout by the promotion of a free and full flow of water through the blood duly eliminated by the kidney. I next pass to the subject of diet and regimen.

What ought the gouty to eat and drink, do and wear? It would perhaps be too crude an answer to this grave question, to say what they like and what *likes* them, that is agrees with them; and yet if we were to argue for a month this is precisely what the outcome would amount to. There is positively no such thing as "a diet for gout," I doubt whether there is really a strict diet for any disease or disorder. I agree with the American physician who lately affirmed that there never was a dyspeptic cured by dieting. I do not deny that it may be possible to find relief in what is called dyspepsia (or difficulty in digesting) by the avoidance of anything and everything which offers the least obstacle to solution and absorption; but, in the same way, it could be possible to find a *modus vivendi* with a broken leg by carefully abstaining from the least endeavour to use it. There is a great deal of inbred perversity in the organism, and if it be too much humoured, or if any great concession be made to its pretences of incapacity, matters are apt to go from bad to worse until at length it will not discharge its functions in a manner consonant with the conditions of comfort or even a tolerable life. I can fancy how this remark will excite the scorn of the single-minded pathologist who looks for some organic fault or lesion as the *cause* of every abnormal state, forgetful of the fact in evolution and development that the environment elicits an attempt to comply with its exigencies, and that the organism is progressively modified by adaption to the function it is striving to perform, so that organisation is really secondary to function, and no inconsiderable proportion of the morbid anatomy discovered by the student of pathology, is the consequence and not the cause of the disorderly action he attributes to it.

We do not give enough attention to this view of the relation of cause to effect, in dealing with pathological conditions during life. Disorderly habits are themselves the sufficient causes of much that is regarded as "organic disease." Difficult digestion, assimilation, impaired nutrition and defective disassimilation, are often in their origin simply disorderly habits of the organism, and these errors of functions when they are formulated will *develop* the organic changes that constitute disease. If we recognise this fact and bear it in mind it will be easy to see that "giving way" to such habits, and even encouraging them by diet and treatment may do mischief. When people tell me they *cannot* eat and drink ordinary food and beverages, I make a point of inquiring curiously into the grounds of their belief in impossibility, because I have had patients who could not possibly eat eggs having never, as a matter of history, tried to take them. They have told me they could not and believed it to be so until on making the experiment, they found the particular articles of food suit them excellently well. I believe one half the "cannots," and "disagrees," are purely imaginary. If they have a real existence—setting aside absolute idiosyncracies, which are very rare,—they are tokens of something amiss which ought to be grappled with, not avoided by a dietary which is either empirical or an embodiment of the weak principle of compromise. I do not for an instant deny that there are cases in which we cannot hope to do more than devise a way of making life tolerable by finding a *modus vivendi* with disease; but to justify the recourse to this expedient it must, I conceive, be ascertained beyond question that the disease so treated is *incurable*. To adopt this method in all cases is simply a trouble-saving routine which glosses over a fault and deceives both patient and doctor.

The sufferer from gout needs above all things to be well nourished and to this end he must be well, though wisely fed. Weakness is the condition above all others to be dealt with in gout. How many lives are lost by placing the gouty on a diet from which meat has been excluded, because, forsooth, there chance to be a little albuminuria or some gouty dyspepsia; although the presence of a trace of albumen in the renal excreta of gouty patients is one of the very commonest of experiences, and in the majority of cases it means nothing more than imperfect disassimilation the prognosis being favourable. We doctors make woful mistakes in the importance we attach to certain phenomena which we regard as pathological simply because we do not make it a practice to examine the excreta in *all* cases. To do this would "take too much time" and so we test only for such things as we expect to find in particular cases. If we examined thoroughly in all cases, we should find the very same things to which we are sometimes directed by symptoms in cases where there were no such symptoms, because the symptoms and the phenomena associated have no necessary or constant connection. It is just and expedient that the sick should know this, and attach due importance to it. Many a condemned patient has actually nothing more momentous to struggle against than his neighbours.

Meat in fair quantity, say from 6 to 8 ounces twice daily on the average, (or 10 ounces for men living ordinary lives), and more for those who are much worried or who work their brains heavily; with fish, soup, bread, potatoes and a fair supply of other vegetables, and fruits, particularly those which are slightly acid, ought to be looked upon, as an indispensable diet. There should be no fixed rule of life, and above all things, there should be no great monotony in the way of living in gout. The digestive organs resent any attempt to coerce them into what is thought to be good behaviour, and loss of appetite, flatulency, and sleeplessness result. Sufficient exercise, by walking and riding, especially is desirable; but extreme fatigue should be avoided. I have deferred what I have to say about stimulants until this point, because their abuse is generally connected with the sense of fatigue and exhaustion. I believe some stimulant is almost invariably requisite in gout, but what is taken ought to be *taken with food.* It is not in my experience, wise to take whisky or any other proximate form of alcohol, wines are far better. For ordinary purposes, I recommend the lighter white wines, such as hock; with dinner a fairly good claret, after dinner an old port, matured in the wood, not left in cask so long as to lose all its goodness, but long enough to ensure perfect maturity of the fermentative process; very good madeira, of fair age, is also an excellent wine for the gouty. I do not think as a rule sherry is to be recommended. Champagne, if fairly dry, *i.e.*, not heavily liquered, is very desirable as an occasional wine. It contains a relatively small proportion of alcohol; but as a rule the dyspeptic find that it produces, or increases, flatulency if taken habitually. As to quantity: two glasses at dinner, and one after; a glass-and-a-half at luncheon or a tumblerful of Pilsener beer, with a glass of claret or port wine and water, with a biscuit before retiring to rest when either the hour is late or much fatigue of mind or body has been incurred since dinner, may be regarded as an average rule of habit. It is a mistake to go to bed with the stomach empty, if there be any sense of exhaustion, or if, as so often happens in gouty cases there is a tendency to sleeplessness. To remedy the latter evil, a most grave one when the habit of wakefulness is formed, a moderate and light supper of fish or whipped eggs, but with little bread, which takes a very long time to digest —is desirable. The clothing of the gouty should be light, and not too warm. This is, I have been led to conclude by experience and observation, a most important matter. The organism should be encouraged, and even compelled, to maintain its natural temperature, in spite of ordinary losses by radiation. Heat-production is one of the functions which stand in special need of the stimulus of habit. If the body is fairly, but only moderately clothed, there will be a proportionately large consumption of fat and sugar to serve as fuel, and the liver will be kept well up to its work, whichi s a point of the very highest moment. The rheumatic—popularly so-called but really the gouty who think they suffer from rheumatic pains—may do well to envelope their bodies in thick flannels, but the gouty will, I am convinced, act more wisely if they strive to maintain their body-heat by brisk movement and a good circulation. In short, as regards eating, drinking, exercise, and clothing, I think the life of the sufferer from gout ought to be above, and before all other things, *natural.*

Every day's experience strengthens my very strong conviction that nothing whatever is gained, but, on the contrary, much is lost, by attempting to lay down a Rule for the gouty. They are emphatically lawless people. Each one has for himself alone to live down his disease, and he can only do this by making health *with happiness* his object. If he think only of health as the prize and makes sacrifices to secure it he will fail. A happy life is quite as important as a healthy one, and it is distinctly not true that the two ideas are inseparable. A sanitary life is very often a very sorrowful one. The gouty need bright and cheerful surroundings. The brain is not only the organ of the mind but the centre of the nervous system, and if the mind becomes depressed or moody, the brain gives away, and the body follows suit. Beyond the hints I have tried to throw out for the management of the patient who suffers from gout we shall do wisely if we can induce him to abstain from considering himself an invalid, and if we refuse to treat him as one.

The outlook from the patient's point of view in gout ought not to be gloomy, above all, it should not be one conceived in a spirit of resignation to the malady. There is nothing less reasonable or expedient than that the gouty should look upon the disorder which causes them so much distress as incurable. It is not in any proper sense a *disease*, although no affection better merits the term in its literal meaning. Gout is, strictly speaking, a morbid habit, and like other habits, this one ought to be struggled against, and reduced, if not eradicated. The aim of the sufferer should be to rid himself of his burden, not by dosing himself with physic or living the life of an ascetic, but by establishing a habit of health throughout his organism. This is not to be accomplished by self-mortification, but by taking such precautions as are necessary to counteract the mischievous tendency of the gouty habit, and then *living* earnestly and actively a life of hope, energy, and rational liberty. People may worry themselves into illnesses by the very measures they take to avoid them, and such worrying is very commonly *the* cause of successive attacks of gout. Linnæus was wise in his generation when he set to work to cure himself of the gout by eating wild strawberries and succeeded. One last word of warning against a particular practice of self-dosing to which the gouty are especially prone. Under pretence of "unloading the liver" they use purgatives recklessly. When the fluid is thus diverted from the kidney the uric acid accumulates and an attack of gout is precipitated.

◆

PREVENTIVE MEDICINE AND ABORTIVE TREATMENT.

By C. R. ILLINGWORTH, M.D. Ed., M.R.C.S. Eng.,

Medical Officer for the Rishton District, Blackburn.

(Continued from page 94.)

According to M. Pasteur and other eminent scientists, every fermentation has its particular organic ferment. It has yet to be shown, however, that it is impossible for animal or vegetable tissue, by the oxidation or other chemical change of its constituents, to develope a chemical ferment which shall, by its action upon the debilitated or degenerate elements of that tissue, produce micro-organisms. The line drawn between chemical and organic fermentations is in fact too hard and fast; and I am of opinion that experiments should be directed with a view to determine the possibility of such a relationship existing between chemical ferments and animal tissues, as I have suggested. It is no proof that because certain micro-organisms, on injection into the blood or tissues of an animal, produce certain diseased conditions, that the particular organisms themselves have not been produced originally by a chemical ferment acting upon such lowly-organised tissues as granulations and pus, or upon the more highly organised tissues, when, though free from micro-organic life, their vital energy has become prostrate by disease, debility, or injury. I go further. I question the existence of any organic ferment.

It is, I think, to the many and varied processes of chemical fermentation we must look for an explanation of the numerous diseases and phenomena caused by germs. The differences observed between one disease and another depend in my opinion not only upon the kind of fermentation, but upon the seat of the fermentative process; whether in the blood, in the tissues, or in material altogether external to the human organism.

The result of these fermentative processes, sooner or later, in such degenerate or debilitated tissues, I hold to be the same in all—the development of micrococci or bacteria. These organisms, by invasion of the tissues from the seat of their development, cause disease in the form dependent upon the nature of the ferment and the seat of the fermentation. In rheumatic fever, for instance, the seat of the fermentative process is in the blood, debilitated by exposure of the system to any condition which may induce the febrile state. As an example of a fermentative process in the tissues I may instance erysipelas, where, in a wound or breach of surface, fermentation is set up amongst the discharges, with the result of development of bacilli. These invade the surrounding parts and thus cause acute inflammatory action, firstly from the irritation excited by their presence, and secondly by their liquefying action on the constituents of the tissues, an action similar to that of "comma" and other bacilli on gelatine and other cultivating media. This irritation and liquefaction explains the diarrhœa of typhoid also; the entrance of the typhoid bacilli into the mucous membrane of the parts of intestine affected being the cause. Other examples of the development of micro-organic life by fermentative processes taking place in the tissues are found in hydrophobia and septicæmia.

As instances of the same processes taking place in tissues altogether external to the human organism, we have those by which are produced the germs of scarlet fever, measles, and diphtheria. It is, I think, more than possible that the germs of these diseases have their origin in fermentations amongst degenerate vegetable tissues, or a mixture of vegetable and animal tissues. Certain it is, however, that the micro-organisms resulting have such vitality and power of proliferation that they are able literally to take root upon sound mucous surfaces, and thus, by their consequent development and absorption, to set up diseases peculiar to each form of germ.

In some cases the process of fermentation itself gives rise to disease, irrespective of the subsequent germ-formation. This occurs in cholera and diarrhœa, both the direct result of abnormal fermentative processes in the digestive tract, and both frequently requiring treatment of a special nature for the destruction of bacilli, developed as a result of the process, which have penetrated into the substance of the mucous membrane of the intestine.

In other cases, again, micro-organisms are developed by fermentation amongst the products of disease, which, so far as has yet been ascertained, are powerless to produce disease in the human organism. Of this nature are the tubercle bacillus of tuberculosis, and the pneumococcus of pneumonia.

The practical outcome of such a theory of diseases of this nature is important, inasmuch as the treatment of them becomes at once either antifermentative or germicidal, and sometimes both combined. By the early application, for instance, of pure phenol in glycerine to an ulcerated nostril before the first symptom of erythema on the corresponding cheek, an attack of erysipelas may be prevented. In twelve cases of erysipelas of the face which I have attended during the last year, I have found ulceration of the nostril. I cured all of them very rapidly by applying carbolised glycerine (1 in 10) to the ulcerated part, and rubbing a 1 in 12 zinc and glycerine ointment well into the erysipelatous patches, whilst I fortified the blood with the time-honoured steel in full doses. By the administration of carbolic acid in premonitory diarrhœa, an attack of cholera may be averted, by checking the abnormal fermentation which has commenced. By the thorough use of pure phenol to every portion of a wound caused by a rabid dog, for the destruction of the ferment lodged there by the bite, all fear of an attack of hydrophobia, from the formation of invading micro-organisms, may be removed. Such are instances of the power of preventive medicine.

To give examples of abortive treatment by germicidal remedies, I might mention that of scarlet fever and diphtheria, where, by the administration of the biniodide of mercury every two hours, in solution of potassic iodide, those germs which have found an entrance to the circulation, and whose presence there is indicated by the scarlatinal rash and enlarged cervical and submaxillary glands, are rapidly followed and destroyed, with the grand result of rapid restoration to health, and the prevention of those fearful sequelæ to which multitudes have fallen victims.

The treatment of syphilis by the biniodide is another example; but I have said enough to indicate the importance of the question of fermentation and germ-origin as bearing on the treatment of disease.

◆

A MODIFIED FORM OF URETHROTOME.

By WILLIAM JAMES FLEMING, M.D.,

Surgeon to the Glasgow Royal Infirmary.

A large majority of surgeons are agreed that internal division is the best treatment of many strictures of the urethra. Of the innumerable instruments for the performance of this operation which I have seen or been able to find described, all of them, while possessing many good and ingenious qualities, have had also some one or more faulty features. My aim has been to combine in one instrument all the good and eliminate all the bad points, so that I do not claim for my instrument many original features, only that it possesses the merits and avoids the faults of its predecessors.

There seems to me to be required in a perfect urethrotome at least seven qualities, viz.:—

1. To be used with one hand.
2. To cut either from before back or from behind forward.
3. To incise any part of the circumference of the urethra.
4. To be easily regulated so as to cut to any depth, even when the blades are out of sight in the urethra.
5. To be of the smallest calibre possible when the blades are sheathed.
6. To be adapted to carry a guide bougie.
7. To be easily cleaned.

The value of the first of these may not be apparent, but with one hand you have a much more delicate sense of touch, which is all you have to rely upon in this operation. Who would hold a probe or a catheter, with both hands? It is also advantageous to be able to grasp and steady the urethra with the free hand. To attain this the projection of the knives must be produced by flexion of the fingers, because this is more powerful than extension, and much more completely under our control, —I presume in consequence of our habituation to use all instruments by the aid of the flexor muscles.

That this instrument possesses the other qualities of a perfect urethrotome as given above will be seen from the following description:—

It consists essentially of a jointed knife (A, Fig. 1), which can be projected from a sheath (B) to regulated distances. This is effected by pressure on the button (C, Figs. 1 and 2), which is continuous with the steel rod (E, Fig. 2), tightly fitting the tube (F), the end of this rod being the knife (*a*), and the rod being reduced and tempered for a short distance from the knife. The other blade (*b*) also runs into a fine tempered endpiece, which rests against the solid probe point either straight (H) or curved (H'), which screws on at (*o*). The blades are withdrawn on removal of the pressure by the spring (K, Fig. 2). The extent of projection of the knives is regulated by the graduated wheel (L) turning on the screw (*d*), and held in place after setting to the required number (French gauge) by the spring wedge (*c*). The whole tube (F) carrying the knives is only slotted for a short distance, and the steel rod is squared and fitted to a square box at the point (*f*, Fig. 2). To clean the instrument screw off H, turn the milled head (C) until the two parts of the rod which are united by a screw at (k, Fig. 2) are separated. The anterior part of the rod with the blades can then be drawn out at the end (*o*). The spring box unscrews at (*m*, Fig. 1).

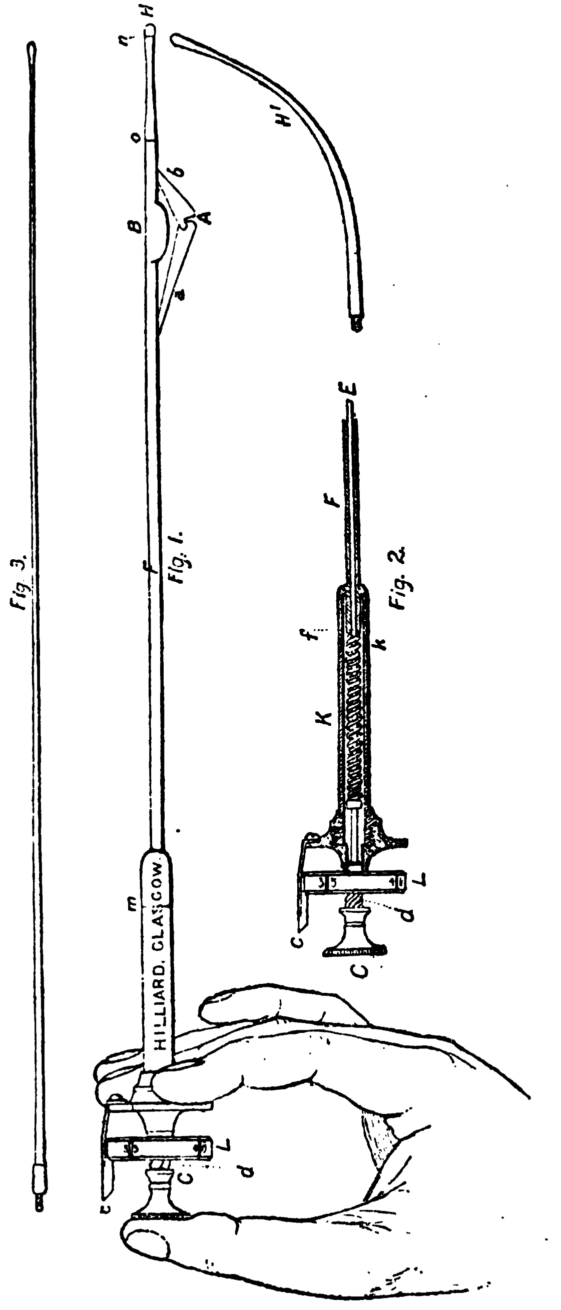

Fig. 3 is the conducting bougie, which can be screwed on at (*n*, Fig. 1) in place of the probe point.

The tube carrying the knife-rod is only slotted for 2¼ inches, and is thus rigid. The square socket at (*f*, Fig. 2) prevents twisting of the knives. The instrument has been most satisfactorily made for me by Messrs. Hilliard and Son, Renfield Street, Glasgow.

Clinical Records.

CHARING-CROSS HOSPITAL.

Under the care of Mr. J. Astley Bloxam, F.R.C.S.

Case I.—*Fracture of Patella—Fragments wired four weeks after.*

Susan C., æt. 20, cook. On the 8th October patient fell down four steps on to her right knee on the stone pavement. She came to the hospital two days later with considerable bruising and ecchymosis of the knee, and as a fracture of the patella was diagnosed, she was advised to come in. This she refused to do and returned home. She could walk with the leg fully extended, but could not extend it when flexed. The swelling and ecchymosis gradually disappeared until last Sunday, when she knocked the damaged knee against the door-post and the swelling immediately returned. She was, however, still able to walk, and came on foot to the hospital on Oct. 28. This time she consented to become an in-patient. The right patella was found to be fractured about the middle, and the fragments well apart and freely movable, no crepitus. There was, moreover, a good deal of effusion into the joint. The joint is swollen, and this is particularly well-marked at the sides of the ligamentum patellæ. Splints were applied to secure immobility, and an ice-bag applied to the injured knee.

Nov. 8th.—To-day, the patient being under ether, Mr. Bloxam made a longitudinal incision over the centre of the patella about two and a-half inches long (under the spray) exposing both fragments of the patella, between which an interval of more than half an inch was seen, filled with clotted blood. This was removed as far as possible. A hole was then drilled in the lower fragment, the external aperture being about a quarter of an inch below the broken edge. The instrument used was a trocar with its canula, so that the wire could be passed without difficulty when the trocar was withdrawn. The canula, however, was so tightly gripped that it broke on an endeavour being made to remove it, and some trouble was experienced in withdrawing the fragment left in the bone. The upper fragment was bored with a bradawl. The wire was then passed through and the fragments brought into close apposition, the ends of the wire being hammered down. A counter opening was made on the outer side of the joint, and a drainage tube passed through it. The external wound was then closed by sutures. An antiseptic dressing was applied, and back and side splints put on, the whole being suspended from a cradle. Evening temperature 99·6° F.

9th.—Morning temperature 100°, evening temperature 100·4°.

10th.—Patient is free from pain. Dressings left undisturbed.

12th.—To-day the dressings were removed under the spray. The wound over the patella looked perfectly healthy. There was a quantity of sanguineous discharge. The wound was cleansed and the drainage tubes shortened. The dressings were then reapplied. Temperature normal.

14th.—The knee was dressed again to-day, there is scarcely any discharge, and everything is going on well.

17th.—The sutures were removed to-day and the drainage tubes further cleansed and shortened. The wound is now almost healed.

22nd.—There is still some discharge. The drainage tubes were now taken away altogether. Temperature normal.

24th.—The splints were removed and the limb placed on a pillow, much to the patient's comfort.

Dec. 1st.—The limb has not been touched for a week. The antiseptic dressings were now discontinued.

5th.—Patient was allowed to get up for the first time with a back splint to preserve extended position.

15th.—Instead of a back splint a gutta-percha splint was adapted to the knee, and the patient was then allowed to walk about.

20th.—Patient was discharged to-day with directions to be careful how she used her knee for some time to come.

Case II.—*Transverse Fracture of Patella—Wired.*

John C., æt. 46, carpenter, was brought to the hospital on Jan. 5th, 1884. He said that while coming downstairs at Her Majesty's Theatre he felt a "click" in his right knee, followed by severe pain, but he did not fall. Immediately after the accident he felt the bone projecting at the front of the knee, but he walked to the hospital supported on the right side by a comrade. He fainted twice in ten minutes on his arrival in the accident room. Within half an hour the knee-joint was already distended to some extent with fluid, and the fragments of the patella were separated about three-quarters of an inch. The limb was put up on a splint and evaporating lotion applied.

Jan. 9th.—The joint is much distended with fluid, and the skin is a good deal discoloured on each side.

10th.—This afternoon Mr. Bloxam cut down and wired the patella. On opening the joint it was found full of blood, which was sponged out. The upper fragment was lying flat on the femur, but the fractured surface of the lower fragment was turned forwards, so that its articular surface was opposite the fractured surface of the upper fragment. The edges of the incision were brought together by means of horsehair sutures, a drainage tube being inserted into joint on the outer side and into wound over patella. The operation was conducted under strict antiseptic precautions.

16th.—Patient has been doing very well, and has had no pain in the knee. Temperature has not exceeded 99·5° F.

22nd.—The wound is dressed antiseptically every day at present, but is rather slow to heal. There is very little discharge.

Feb. 4th.—Drainage tubes removed since the 2nd, and the wounds are now healed.

15th.—The patient is allowed to get up with a back splint on, and he can walk without pain. He was made an out-patient on the 24th.

◆

SESSION OF
The General Medical Council.

In our last issue we gave the proceedings of the Council up to and including the sitting on Saturday before going to press. We now give a *précis* report of the remainder of the session.

MONDAY, February 21st.

The President, Sir Henry Acland, in the Chair.

The Apothecaries' Societies and the Conjoint Scheme.

In opening the business for the day, the President mentioned that he had consulted with the Chairman of Business and also some other members of the Council as to the mode to be adopted in bringing the resolutions of the Council before the Royal Colleges, and, with the permission of the Chairman of Business, a resolution would be moved on the subject.

The following is the resolution referred to, which was then brought forward by Dr. Struthers "That the President be requested to communicate to the King and Queen's College of Physicians and the Royal College of Surgeons of Ireland, and the Apothecaries' Hall of Ireland, the resolution of the Council of Feb. 16th, and to communicate to the Royal College of Surgeons of England, and the Society of Apothecaries' of London, the resolution of the Council of Feb. 19th, and to take such further action as he may see fit towards the attainment of the object of those resolutions, to which the Council attaches great importance, in the interest of the public."

Mr. Wheelhouse seconded the motion.

Dr. Aquilla Smith objected to the motion.

Mr. Brudenell Carter moved an amendment to the effect "That the letters, if any, to the Royal College of Physicians, London, and the Royal College of Surgeons, England, be addressed to the President of those Colleges respectively, with the request for immediate reply, and that those replies be considered by the Council during its present session."

The motion and amendment were by the rules of the Council adjourned to the following day.

THE VISITATION OF EXAMINATIONS.

Dr. **Bruce** then moved the following amendment to the motion of Dr. Heron Watson with regard to the report of the Visitation of Examinations Committee—"That in receiving the final report from the Visitation of Examinations Committee, the General Medical Council is happy to find that all the universities do provide a sufficient guarantee that their graduates possess the requisite knowledge and skill for efficient practice of their profession."

He remarked that unless Dr. Watson was prepared to move an amendment to some of the rules and regulations of the Council, which would be the logical sequence of his proposal to go into committee, the course he had suggested would be a mere waste of time. It had often been said to the direct representatives on the Council during the progress of their election that they ought to take care that no man who was not a gentleman and had not the making of a good doctor in him should be admitted to the profession. But that was not the function of the Council. No resolution of the Council and no Acts of Parliament would make a man a gentleman. The Council was not a patent machine for turning out irreproachable doctors. All that it could do was to see that candidates came up to a certain minimum in their examinations.

Rev. Dr. **Haughton**, in seconding the amendment, said, it had not been proved to the satisfaction of the Council that any one corporation or university in the three kingdoms was letting loose upon the world men who were not safe practitioners. That was their business and that alone. On reading over the reports, he did not see any case had been made out to satisfy any individual member, much less the Council as a whole, that in any instance these bodies had passed men who were incompetent to practise.

Mr. **Simon** disapproved both of motion and amendment, and moved the following:—"That the Council, intending shortly to begin its inspections under the Medical Act of 1886, will, when it enters on that duty, particularly direct the attention of its inspectors to all points at which the late Visitors of the final examinations of the universities take exception more or less to the sufficiency of certain of those examinations, and will on the same occasion take a like course in respect of the reports which it last received on the examinations of the medical corporations."

Sir **Wm. Turner** said he could not accept what he understood to be the proposition laid down by Dr. Heron Watson—viz., that these various documents had not been properly discussed in the Council, because on page 3 of the revised reports he found that the documents which the committee had before it consisted of certain instructions prepared by order of the Medical Council for the instruction of their Visitors; secondly, of the reports of the Visitors; and thirdly, of the discussions held on June 7th, 8th, 9th and 10th, in committee of the whole Council. He could not see any reason at all why Dr. Heron Watson should now ask them to go into committee on documents on which the Council had sat in committee on four full days in the month of June. He submitted that the Council ought not to take up such a position as to render it necessary for members to remain away from their home duties any longer than was absolutely necessary.

Dr. **Glover** contended that the subject had not been fully disposed of at the last meeting of the Council; the amendment of Dr. Bruce (which damned the universities with faint praise) was a very inadequate outcome of the visitations which had taken place by men of the highest eminence. In one of the reports it had been distinctly stated that the examiners had erred on the side of leniency, and in three cases, as Mr. Simon had pointed out, the examinations were not considered sufficient to guarantee the requisite knowledge on the part of the persons passed. He should, however, vote for Mr. Simon's amendment, seeing that the Council was about to turn over a new leaf and to undertake very critical inspections with a view of securing a more severe standard than formerly existed.

Dr. **McVail** said that the majority of the Council had evidently made up their minds not to deal with the reports, because if any opinion were given by the Council a number of institutions would be severely censured before the profession and the public. If there was any waste of time, it would be in not considering the reports, the drawing up of which had involved so much trouble and expense.

Mr. **Macnamara** accepted the principle of Mr. Simon's amendment and should vote in its favour.

Dr. **Leishman** said that Mr. Simon's amendment had relieved him from a great difficulty. He sympathised with a good deal of Dr. Heron Watson's statement, but if the subject were to be fully discussed, he did not know when it would be ended.

Dr. **Banks** stated that one of the three cases cited by Mr. Simon had reference to the University of Dublin, and that in that case the examination was for physicians, and not for general practitioners. The Visitors stated that they were favourably impressed with some portions of the examinations, and could conscientiously commend the specially medical portions.

Dr. **Struthers** said that the whole subject had been thoroughly threshed out, and he repudiated the insinuation that he was afraid of further discussion.

Dr. **Heron Watson** having briefly replied, Mr. Simon's amendment was put and carried, and it was also carried *nem. con.* as a substantive motion.

PROPOSED ALTERATION IN THE EXAMINATION OF STUDENTS.

The next business was moved by Mr. **Teale**: "That in the opinion of the General Medical Council it is desirable—(*a*) That, in the interest of students whose place of medical education is at a distance from the seat of examination, the written portion of the examination should be conducted at the place of education; (*b*) that a sufficient time should intervene between the written and the oral portions of an examination to allow the examiners to read over and judge the written answers of every candidate, and to confer upon doubtful cases before the commencement of the oral examination; and (*c*) that candidates who in the written examination have failed so completely as to have forfeited all chance of passing by the aid of the oral shall be "stopped" from passing on to the remaining portion of the examination. This step ought to be granted as a matter of economy of money in the case of students, and as a matter of economy of time in the case of examiners.

Mr. **Simon** rose to order. He said it was the duty of the Council to mind its own business, and this was not its business. It was a question in contest between parties independent of them, and over whom they had no control. It was merely as to questions of internal economy between independent examining boards and their students.

The **President** ruled that the motion was in order. It was merely another form of recommendation, and that was a matter quite within the province of the Council.

Mr. **Mitchell Banks** seconded the motion. He thought that in justice to the provincial students in England some means should be adopted by which their examinations might be lightened. Examination papers could be easily and safely sent through the Post Office, and the heads of the colleges and schools might be thoroughly trusted to see that the examinations were fairly conducted.

Dr. **Moore** said that there were practical difficulties in carrying out Mr. Teale's proposal. Students sometimes, while writing their papers, would ask for some explanation respecting a question, and if the examiner were not present, the explanation might not be satisfactorily given.

Rev. Dr. **Haughton** said that in Dublin it was always considered necessary to have the examiner present at an examination for honours; but that was hardly necessary in the case of a pass examination.

Dr. **Banks** referred to the dangers attending the transmission of the papers. In order to obtain absolute security in this regard, the authorities at Trinity College, Dublin, had decided to have a printing press on the premises.

Mr. **Wheelhouse** said there was a very strong feeling amongst provincial students that injustice was done them in regard to their written examinations. Even when there was no chance whatever of their passing in their written papers they were detained in London for days to go through the oral examination, which could only be a farce. The present method, he considered, added at least £10 to the cost of a diploma for a provincial student.

Dr. Heron Watson moved the previous question, and said he considered it a waste of time to discuss the subject, and Mr. Teale's resolution was negatived by 11 to 9.

The Unqualified Assistant Question.

On the motion of Mr. Marshall, seconded by Dr. Heron Watson, the report of the Executive Committee in regard to Dr. Day was adopted. The committee recommended that "before proceeding further in the matter, it would be desirable to refer the papers on Dr. Day's case, with the Report on the Uses and Abuses of Unqualified Assistants presented by the committee appointed by the General Council on July 3rd, 1882, and the resolution passed by the Council on April 21st, 1883, to the Privy Council, and to communicate the result of such reference to a future meeting of the General Council."

Mr. Marshall then moved: "That the diplomas in sanitary science, public health, and state medicine, granted after examination (see pp. 46-71 of the Minutes for February 15th, 1886) be recognised by the Council for purposes of registration in the Medical Register, under Section 21 of the Medical Act, 1886."

Rev. Dr. Haughton seconded the motion.

Dr. Glover asked if anything could be done to introduce something like uniformity in the titles.

Mr. Marshall said they had taken a legal opinion on the subject, and were distinctly instructed by their solicitor, and also by Mr. Muir Mackenzie, that they had no power in the matter. They were compelled to use the title that the body itself used. If it was an evil, it was not an evil of the Council's creation, and it was not for them to exercise any influence in the matter.

The motion was agreed to,

Presentation to the President.

Dr. Humphry said the very agreeable duty had been deputed to him of offering a marble bust to the President for his acceptance. That bust, executed by M. Boehm, was presented by the members of the late Council and others, who had at various times sat under Sir Henry Acland presiding at the table; of those, alas! some were unable to be with them in their bodily presence, of whom he might name Dr. Scott Orr, Dr. Apjohn, and Dr. Storrar. The mention of those names recalled the names of others who also had at still earlier periods sat at that table—Dr. Embleton, Dr. Allan Thompson, Sir Dominic Corrigan, Dr. Rolleston, Dr. Sharpey, and Dr. Andrew Wood,—and there could be no doubt that every one of those would have rejoiced in any opportunity of doing honour to their President. There was no person who had been so identified with the work of the Council up to the present, and it was scarcely probable that any other person ever could be. Ever since its first institution in the year 1858 he had been a member of it, and for more than twelve years he had been its president. The presentation was made as a mark of their high regard for their President as such, and their no less high esteem for him as a man. It was also a token of the general wisdom of his administration in that chair, and of the untiring, continuous, unselfish devotion which he had given to the work of the Council, Dr. Humphry also referred to the work carried on by their President in the University of Oxford, where it was he who first opened the springs of natural science, which afterwards flowed to Cambridge, while from those two universities fountains had been opened in various parts of England, which had done much to promote a higher and more extended education. He concluded by assuring the President that whenever he should cease to bear that honoured name he would be remembered with affection and regret.

The President, in acknowledging the gift, referred to his long connection with the Council, and said it was rather remarkable that, considering the uncertainty of things here, he had never been absent from any sitting of the Council except on one day when he was obliged to be at Oxford. In conclusion, he asked the favour of the Council to accept the bust, and allow it to remain in the Council room.

Dr. Humphry, on behalf of the Council, accepted the bust, and said that they hoped shortly to add to it the bust of Sir Henry's predecessor, Dr. Paget, so that both universities might be fitly represented.

This concluded the proceedings for the day.

TUESDAY, February 22nd.

The President, Sir Henry Acland, in the Chair.

Removal from the Register.

The first business of the day was to direct the Registrar to remove the name and qualifications of Mr. William Edward Robson from the Medical Register, such qualifications having already been withdrawn by the Colleges of Physicians and Surgeons of Ireland, as previously reported in this journal.

The Apothecaries Society and the Conjoint Scheme.

Dr. Struthers then moved the resolution of which he had given notice, and which will be found in Monday's proceedings. He said it was not to be supposed that the President should exercise any undue influence or pressure, but if he would kindly undertake these good offices it might be of very material service to the bringing about of a harmonious solution of this very important point. In looking over the letters that had passed, he thought he saw a ray of hope, notwithstanding all that had been said.

Mr. Wheelhouse seconded the motion. The matter was one of very great importance to the profession at large, and in trying to carry it to a successful issue the Council should leave no stone unturned.

Mr. Macnamara, while sympathising with the desire that had been expressed, was afraid that hope had told a flattering tale. From letters which he had received from Dublin, he feared that the two Colleges would not listen to the charmer, "charm he never so wisely."

Mr. B. Carter proposed an amendment omitting all reference to the English bodies. He contended that any efforts in relation to those bodies would be a waste of time on the part of the Council, and might inflict serious injury on the Society of Apothecaries. It was necessary that that Society should have ready by June 1st an examination which might with confidence be submitted to the Council, and examiners would have to be appointed either by the Medical Council or the Privy Council. The time, therefore, would have to be fixed—a time beyond which the inaction of the Council would be interpreted as a refusal, and when application would have to be made to the Privy Council. It was not right to hang up the Society of Apothecaries between heaven and earth, like Mahomet's coffin, between the present time and the next meeting of the Council, whenever it might happen to be. The Society did not object to competition, but it claimed to be treated with simple justice. The proposed delay would be a profligate waste of time, and the efforts made would be absolutely futile.

Rev. Dr. Haughton, in seconding the amendment, said he had hopes with regard to Dublin; but from all he had heard in England he thought that the proposed action would be a mere waste of time.

Sir W. Foster opposed the amendment on the ground that the Council had no right to look outside its own body in the matter. He could quite understand that the Apothecaries' Society would be delighted to be put in an independent position, but he thought the Council ought if possible to prevent it.

Sir William Turner said the Council had already seriously considered all that was involved in Mr. Brudenell Carter's amendment, and therefore his impression was that the whole of this was out of order.

The amendment of Mr. Carter having by leave been withdrawn, the motion as proposed by Dr. Struthers was agreed to.

Inspection of Examinations.

The next business was to consider the report by the Inspection of Examinations Committee.

It being resolved to deal with the resolutions in the report *seriatim*,

Mr. Marshall moved the adoption of the first resolution: "That the principle on which the Council's visitation and inspection of examinations ought to be founded is, that the visitations and inspections shall systematically cover, within stated periods of time, the pass examinations in all branches of knowledge which the Council deems essential as qualifications for licence."

Mr. Heron Watson seconded the motion, which was after considerable discussion adopted.

Mr. Marshall moved the adoption of Clause 2: "That reserving for future action the visitation and inspection of the examinations in the earlier subjects of professional education, the first year's appointment of inspectors provide for the inspection of examinations in medicine, surgery, and midwifery."

Dr. Heron Watson seconded the resolution, which was adopted.

Mr. Marshall moved the adoption of Clause 3: "That each inspector to be appointed for any purpose of the preceding resolution (2) to be appointed for all three divisions of the United Kingdom."

Dr. Struthers seconded the motion, which was agreed to.

Mr. Marshall then moved the adoption of Clause 4; "That the Council appoint one inspector representing medicine, one representing surgery, and one representing midwifery—three inspectors in all."

Dr. McVail asked whether, looking to the number of bodies to be inspected, it was considered that three inspectors would be sufficient.

Mr. Marshall said the committee had taken that important subject into consideration. It was felt that they could not afford to pay more than three inspectors during the first year, and hence the inspection was limited to those three subjects. With regard to the work they had to do, there were fifteen bodies only to be examined in the three divisions of the kingdom, and those fifteen bodies surely could be inspected in the course of the twelve months.

The resolution was agreed to as were also the subsequent resolutions: "That, previously to making appointments, the Council invite suggestions concerning them from each Branch Council. That each inspector make, from time to time, such inspections of the examinations in his special subject, held by the several licensing bodies in the United Kingdom, as may enable him to form an opinion upon, and report to the Council as to the sufficiency or insufficiency of those examinations; and, further, that he enter in a diary the date of and the time occupied in each inspection, and any observations that he may think fit and present this diary, with a report as to the sufficiency or insufficiency of the examinations of each body so inspected by him, to the General Council annually, or at such times as may be required, and that the remuneration for these inspectors be by annual payments."

Mr. Marshall then moved the last resolution contained in the report: "That the inspector in medicine, and the inspector in surgery, appointed as above recommended, receive for the year's services £300 and certified travelling and hotel expenses, and the inspector in midwifery £200 and certified travelling and hotel expenses."

Dr. Watson seconded the motion, which was agreed to.

Dr. Quain moved, and Sir Walter Foster seconded: "That it be referred to the Executive Committee to make arrangements for carrying out the resolution just adopted, and to report to the next meeting of the Council thereon.'

After some discussion the motion was agreed to.

The President having made a statement to the Council in reference to the communication which the Council had directed to be made to the Royal College of Physicians of London and the Royal College of Surgeons of England, and to the communication which the Council had directed to be made to the King and Queen's College of Physicians in Ireland, and the Royal College of Surgeons in Ireland, and having expressed his intention to resign his office at the close of the present meeting, it was unanimously resolved: "That the President be invited to continue in office until the next meeting of the Council."

The President having consented to adopt this course, the Council adjourned.

WEDNESDAY, February 23rd.

The President, Sir Henry Acland, in the Chair.

Dr. Heron Watson called attention to a paragraph in the *Standard* in reference to an application which had been made in the Queen's Bench Division for a *mandamus* to direct the General Medical Council and their Registrar to restore the name of Mr. Partridge to their Register as a dentist under the Dentists' Act of 1878, the Irish College of Surgeons having, in 1885, withdrawn his diploma upon the ground that he had advertised in the course of his business as a dentist. It was alleged that no authority was given under the Act in question to remove names from the Register on this ground.

The Registrar announced that a letter had been received from the Solicitor in reference to the matter, but before this was read, strangers were requested to withdraw.

The matter was subsequently reported to the executive committee.

Report of the Lord President's Letter Committee *re* Mr. Laffan's Memorial.

The Committee was appointed on Thursday, Feb. 17th, to consider and report on a letter, dated Feb. 8th, from the Lord President of the Privy Council, enclosing a memorial of Feb. 4th, 1887, addressed to the Lords of the Council by Mr. Thomas Laffan, of Cashel, with respect to the efficiency of qualifying examination under the Medical Acts, and requesting the Medical Council to favour his Lordship with their observations in regard to Mr. Laffan's Memorials.

The Committee met three times.

The Committe find the following charges contained in Mr. Laffan's Memorial:

(1) "Inaction of the General Medical Council (as per official Minutes of that body for 1886), on the Report of the Visitors of such body on the examinations of the Royal University of Ireland."

(2) "That the candidates for the degrees of that University are shamefully deficient in clinical training." In support of this charge Mr. Laffan encloses extracts from the Report of the Visitors.

(3) "That the University itself imposes restrictions which stand in the way of the adequate clinical training of said candidates, and that it has declined to remove the same." To support this charge Mr. Laffan submits a memorandum of negotiations of Irish provincial hospital physicians with the Royal University of Ireland.

(4) Mr. Laffan submits for his Lordship's perusal the opinion of the Royal Commission on the Medical Acts on the neglect of the Medical Council to enforce section 20 of the Medical Act of 1858, and prays his Lordship to enforce the 19th section of the Act of 1886 in this matter.

As to the charges of inaction on the part of the Medical Council, it is to be observed that the Council could not, even if they thought it necessary so to do, take any action under section 19 of the Medical Act (1886), as this section has not yet come into force, and will not, till "the appointed day in June."

The fourth charge, that of inaction under section 20 of the Act of 1858, may be most conveniently considered with the foregoing.

That this charge is, in the present instance at all events, devoid of foundation, will at once be made apparent by reference to the Minutes of the Council contained in the same volume (vol. xxiii, 1886) from which Mr. Laffan has made extracts to support his memorial. The Visitors' Reports were received by the Council, and entered on the Minutes on June 1st, 1886, and on the same day a Committee was appointed to prepare a summary of the Reports, together with such comments as the Committee might desire to make.

On the 7th June this Committee presented its first Report, in which the following passage occurs, and is now quoted for its important bearing on the Lord President's request to be furnished by the Council with observations on Mr. Laffan's Remarks as to the efficiency of qualifying examinations under the Medical Acts:—

"It is, however, as already indicated with the conditions attached to the attainment of the Bachelor of Medicine degree that the Committee is concerned; and in this respect it is satisfactory to note that the result of the visitation of the Universities, conducted last year, is decidedly favourable; for, judging not from the opinions of the Visitors exclusively, but from the actual information contained in their voluminous Reports, the requirements and examinations demanded of, and undergone by, candidates for the degree in question at the several universities, are such as, speaking generally, to secure an adequate knowledge for the practice of the profession in its three specified departments of Medicine, Surgery, and Midwifery." (Minutes of General Medical Council, June 7, 1886, vol. xxiii, pp. 83, 84.)

A final Report was received from this same Committee, and entered on the Minutes at the present meeting of the Council, in which the following passage occurs at page 94, and is also now quoted because of its special bearing on the Lord President's inquiry:—

"It will be seen that with few instances of reservation, the Visitors assent to the sufficiency of the examinations witnessed by them; and that in regard to those few instances, the reservations concern only certain parts of the examinations, and are not sufficient to enable their adequacy as a whole to be impugned. On matters of detail the replies of the authorities specifically concerned will usually be found to offer reasonable explanations of the peculiarities of their respective systems. In no case could it be maintained that there was justification for a formal representation on the part of the General Medical Council to any of the Universities, and it is well known that changes and improvements have been and are continually being made in those great institutions, frequently in full accord with the tenor of the Visitors' remarks."

As to the second statement made by Mr. Laffan, viz., that the candidates for the degrees of the Royal University are shamefully deficient in clinical training, it appears to your Committee that Mr. Laffan has, in many important respects, omitted to state the whole case. For the Visitors have expressly drawn attention to the fact that many of the candidates whose answering they found so bad had previously been rejected several times, which may have been largely due to faults in the candidates themselves. Thus of ten candidates whose cases are specified at pp. 412, 413 of the Visitors' Reports (Minutes of General Medical Council, vol. xxiii, 1886), one "had been up three times," and six "had been up twice" previously.

The Visitors further state the rejections were very numerous. "There were," they say, "82 candidates, of whom 40 passed; 37 were rejected; 5 retired. Inclusive of those who retired, it appears that more than 50 per cent. were rejected. This large proportion of rejections proves the imperfect training of the candidates no less than the impartiality and discrimination of the examiners" (pp. 407, 408).

The "concluding remarks" of the Visitors in their Joint Report seem also to have escaped Mr. Laffan's notice, though they express the final judgment of the Visitors on the whole course of the examinations they witnessed, and seem essential to a true representation of the working of the University. They will be found at page 396, and are as follows:—

"The Visitors think that the course of study and the examinations to be gone through in order to obtain the medical degree of the Royal University (having regard to the conscientious strictness with which the candidates are dealt with, and, consequently, the large proportion of rejections) are such as to secure the possession by its graduates of the requisite knowledge and skill for the efficient practice of their profession."

The remaining charge made by Mr. Laffan against the Royal University of Ireland is that the University itself imposes restrictions which stand in the way of the adequate clinical training of said candidates, and that it has declined to remove same.

The authorities of the University have already recognised the value of many of the criticisms and suggestions made by the Visitors, and have adopted the more important of them, thus (see Regulations concerning the Examinations in the Faculty of Medicine for 1887) acting in strict accordance with their previous zealous efforts to raise their standard of education both in arts and in professional subjects.

It appears also from the letter of the 14th of June, 1886, from the Secretaries, quoted by Mr. Laffan, that they have taken into consideration the application of the union hospital physicians to have these hospitals recognised for clinical teaching, and have, for reasons assigned, decided not to accede to the application.

The Committee feel the strongest sympathy with the utilisation of the clinical material in union hospitals, but it is a matter which requires inquiry into the character of each hospital and the material it offers for affording useful clinical instruction. This is a work which cannot be done by this Committee or by the Council, but should be considered and answered by the University itself. From the documents laid before them by the Representatives on the Council of the Royal University it appears the Senate of the University take the same view, and are ready to consider on their merits, subject to regulations which appear to this Committee to be reasonable, individual applications for recognition, though they decline to pass any rules recognising union hospitals generally.

In conclusion, the Committee are desirous of expressing full confidence in the Royal University of Ireland for maintaining the efficiency of its qualifying examinations under the Medical Acts, and in their adopting so far as a non-teaching University can every possible means for promoting the practical training of medical students.

William W. Gull,
Feb. 22, 1887. Chairman.

Sir **Wm. Gull** moved that the Report be received and entered on the Minutes.

Some discussion took place in reference to certain typographical errors and other points, and it was agreed to introduce sundry minor alterations at once, The motion was then carried.

Sir **Wm. Gull** then moved that the Repoit be adopted by the Council.

Mr. **Macnamara** proposed that the Report should apply to county infirmaries as well as to union hospitals. (Sir Wm. Gull said that the matter had been considered and negatived by the Committee.) He said that Mr. Laffan's grievance was quite a sentimental one. The College of Surgeons had long had a rule that six summer months in a provincial hospital should count as three months in a metropolitan hospital, but, with two exceptions, no advantage had ever been taken of the permission.

Dr. **Kidd** called attention to the title signed by Mr. Laffan, "M.R.C.P.I.," no such title existing.

Dr. **Leishman** pointed out that the Royal University of Ireland was a purely examining body, and the criticisms of the Visitors bore upon purely teaching faults. He considered that there was not the shadow of an imputation on that body.

The motion was then put and carried.

Mr. **Marshall** moved that the Report of the Committee as adopted by the Council, be forwarded to the Lord President, and this was agreed.

A subsequent proposition by Mr. Marshall, seconded by Sir Walter Foster, to forward at the same time the first and final Reports of the Visitation Committee, was negatived.

Visitation of Medical Schools and Hospitals.

Rev. Dr. **Haughton** moved "that the visitation of medical schools and hospitals is a pressing question, more especially as regards the requirements and facilities for the practical study of fever and midwifery cases."

The motion was seconded by Mr. **Macnamara**.

Dr. **Leishman** moved, as an amendment, that the Council do pass to the next order of the day, seconded by Dr. **Chambers**.

Rev. Dr. **Haughton** expressed his surprise at the amendments of which notice had been given, and the effect of which would be to block the way. He alluded to the lack of interest on the part of students as regarded fever cases. He thought the licensing boards should seek to enforce a knowledge of these cases, and under the new Act he thought something might be done to ensure that a man on becoming qualified, should be able to distinguish between small-pox and scarlet fever, and should be able, in a midwifery case, to do a little more than an old woman. The subject was one which merited anxious and serious consideration, and he would like to postpone his motion for that purpose.

Dr. **Leishman** explained that his object in proposing his amendment was for the express purpose of securing proper attention to the subject. He would be the last man to block any measure which would have for its effect to facilitate the study of midwifery.

Mr. **Simon** suggested that they should appoint a special committee to consider the question.

Dr. **Banks** agreed with Dr. Haughton's remarks as to indifference of students to fever cases. He mentioned that quite recently at the examination a student had flatly refused when told to report on a case of fever.

Dr. **Leishman** said that the Royal University of Ireland was not the only body which required attendance on fever cases; the University of Dublin had long required the same.

Sir **Wm. Gull** said he hoped such an occurrence as that related by Dr. Banks was exceptional, even on the other side of St. George's Channel, Of course students should be required to become acquainted with all varieties of disease, including fever.

Dr. **McVail** said that a great difficulty existed in the study of fever cases in all large towns, and the practical study of midwifery was not less urgent.

Mr. **Brudenell Carter** said that if more stress were laid on fever at the examinations, students would be more particular.

Dr. **Leishman** then asked the permission of the Council to withdraw his amendment, and this was agreed to.

Mr. **Simon** then moved that a standing committee should be appointed, to be called the "Curricula Committee," to report from time to time on the subjects appertaining to the course of education, under section 16 of the Medical Act, the committee to consist of eight members.

Dr. **Humphry** seconded the motion.

Dr. **Quain** suggested that it would be preferable to await the result of the inspection of schools.

The amendment was negatived.

The original motion was then put to the Council, whereupon Dr. **Struthers** moved, as an amendment, that the question be postponed until the next meeting. It was seconded by Dr. **Banks**, and carried.

Improvements in Medical Education.

Dr. **Glover** moved:—

"That a committee be appointed to consider the best methods of increasing the practical element in medical education, as by a system of limited pupilage with a registered practitioner and insistence on more clinical, therapeutical, and pathological teaching and work in medical schools."

He said there were three or four facts which would justify him in bringing forward this resolution. The first was the very prevalent impression that young men leaving the schools now, were not well up in their practical work. Practitioners complained that they could not get assistants fit to put in charge of a practice on account of their ignorance of dispensing and of the treatment of the common ailments which make the bulk of general practice. He thought the education at hospitals required to be supplemented, seeing that the ordinary run of cases were not met with in hospitals. He drew attention to the large proportion of failures at the final examinations, and quoted the number of candidates passed and rejected by the various examination boards. He thought that these figures showed a terrible defect in the present system. Dr. Duncan had stated that he never knew a good man rejected, but there was plently of evidence to prove the contrary. It was easy to explain the number of rejections by blaming the stupidity or idleness of the candidates, but this did not, in his opinion, meet the case. He was disposed to divide the blame between the students, the schools, the teachers and the Council. Certain schools were, moreover, notoriously wanting in the material for clinical education, and this, he said, was as much the case in London as elsewhere. There were, he said, several great fields of clinical work not in use; first the great field of private practice, then the workhouse infirmaries, lying-in hospitals, &c. He thought the Council ought to make a special mention of the subject of midwifery. In Scotland the examining bodies only required attendance on six midwifery cases, and he asked what was likely to be the position of a man who having done his six cases, came upon an arm presentation, or a case of post-partum hæmorrhage.

Mr. **Wheelhouse** rose to second the motion, and said that from the importance of the subject it would be better to appoint a committee.

Sir **William Gull** said that the student learned in hospitals a good deal of pathology founded on morbid anatomy, but there were a vast number of cases of which there was no morbid anatomy, the pathology of ailments.

Mr. Brudenell Carter, Dr. Heron Watson, Dr. Struthers, and Dr. McVail also spoke on the subject.

The motion was carried unanimously, and a committee was appointed forthwith to consider and report on the subject.

On the motion of Dr. **Heron Watson**, seconded by Mr. **Marshall**, the thanks of the Council were voted to the Directors-General of the Army and Navy Medical Departments, with a request that they would continue to supply the Council with the number of candidates referred to in their respective lists who had two or more qualifications, and the number of those who were passed or rejected.

A table prepared by the Registrar showing the number of candidates and the rejections per cent. at final examinations in the years 1883 to 1886 was received and entered in the Minutes.

This concluded the business of the session.

◆

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

Friday, February 25th, 1887.

Dr. **Broadbent**, President, in the Chair.

Dr. **Hughlings Jackson** read a paper on a case of

PARALYSIS OF THE LEFT LEG FROM SUB-CORTICAL DISEASE, WITH CANCER AND FRACTURE OF THE LEFT FEMUR.

A woman, æt. 52, was admitted December 28th, 1885, under Dr. Hughlings Jackson's care, for paralysis of the left leg, which had come on suddenly on December 7th, whilst she was standing at her work. The knee jerk on the paralysed side was greatly exaggerated, and there was foot clonus; there was no defect of sensation; no morbid changes in the fundi. On December 30th, whilst she was being lifted from the bed-pan, the left femur broke just below the great trochanter. Death occurred January 10th. At the autopsy there was found cancer of the left femur, of the ovary, and of the brain. The brain was examined by Dr. James Anderson, who found several growths in it, one accounting for the paralysis of the left leg, being in the region of Ferrier's leg centre.

Dr. **Broadbent** said that it was interesting to note that the patient died in little more than a month after the occurrence of the paralysis, and yet the exaggerated ankle clonus and ankle jerk had been remarked, although this was generally supposed to result from descending degeneration which could hardly have taken place.

Dr. **Beevor** said the case was of interest as showing the localisation of the leg centre. The posterior part of the marginal convolution was part of this centre. The absence of fits was also remarkable. Mr. Horsley and he were carrying out experiments by stimulating the internal capsule, and they had found that the hindmost fibres went down to the leg.

Dr. **Carrington** read a case of

SUCCESSFUL TREATMENT OF HYPER-PYREXIA IN ACUTE RHEUMATISM, BY THE COLD BATH.

He said that although there was nothing new in the case he brought forward, still he thought it was well to put such cases on record in order to accumulate a body of evidence such as would enable medical men to combat the prejudice existing amongst the friends of patients, against the employment of a remedy which afforded the only chance of safety in this desperate complication. The patient was a medical student, æt. 23, strong and muscular, and hitherto in perfect health. He had been ill with what was apparently a mild attack of rheumatism, for which he had been treated by salicylic acid. He was so far recovered that he had left his bed, and on the evening of October 31st had received the visits of his friends. He passed a good night, and there was nothing to excite attention next day, but on taking his temperature next morning about twelve, noon, quite as a matter of routine, it was found to be 107°. Dr. Carrington saw him soon afterwards, and then found the temperature to be 106° F. He was, as soon as practicable, removed to the private ward of Guy's Hospital, but in the journey had become noisy and delirious, and by the time he had been placed in bed he was quite livid, unconscious, and generally convulsed. His temperature was then found to be 109·8°. The necessary arrangements had been previously made, and he was at once placed in a bath at a temperature of 70°, which was as rapidly as possible cooled down by ice, large quantities were used, but the body heat was so great that there was great difficulty in lowering the temperature of the bath. Pouring ice-cold water on the patient's head had a beneficial effect. A rectal injection of fifteen grains of antipyrin was exhibited. He was kept in the bath for a full hour, and when the rectal temperature was 102·4°, he was removed and placed on a blanket and lightly covered by a sheet. Then marked tetanic convulsions supervened, and he gradually became quiet, and at 7 p.m. his temperature fell to 97·2°. At 8 p.m. consciousness returned, and he took a pint of milk, and at 10 p.m. he was quite rational. During the next day be remained comfortable, and took gr. xx of salicylate of soda every two hours, but his temperature again arose, and at 12 p.m. it was 103·8°. He was given gr. xv of antipyrin by the mouth, but at 2 a.m. the temperature was 105·2°, and the ice-bath was again employed for fifteen minutes. He was taken out when his temperature had fallen to 101°, but at 6 a.m. it had again risen to 105·4° and the bath was again had recourse to for a similar period. After this he slept well, but at 2 p.m. the temperature had reached 105°, and he was bathed again for forty minutes. From this time the temperature never again rose to any extent, it was for the most part normal, but on one occasion with a return of the articular pain it reached 101°. After the third bath salicine was substituted for sodic salicylate, in 25 grain doses every two hours. After two days he took it every three hours, and the dose was gradually reduced. With an interruption due to the slight relapse, the patient made an uninterrupted recovery from this time, and left the hospital quite well. The experience of the case seemed to be that within the limit of collapse, prolonged immersion was more effectual than shorter and more frequent baths.

Dr. **HALE WHITE** said that the failure of salicylate of sodium and antipyrin was of interest, as leading us to see in some manner the way in which those drugs acted. In rheumatic pyrexia, at any rate, they were not of value. It was possible that it would by-and-by be discovered that each drug was applicable to a particular class of cases.

Dr. **BROADBENT** said that he had not seen convulsions occur during the rise of temperature. He had seen them come on during the cold bath in a case which ultimately proved fatal, and he had seen hyper-pyrexia supervene during the use of salicylate of sodium.

Dr. **HUGHLINGS JACKSON** wished to know the exact nature of the convulsions, and particularly whether they were tonic or clonic or both?

Dr. **STEPHEN MACKENZIE** said he had had three or four cases of hyper-pyrexia in private practice, and could endorse the remarks as to the difficulty of the cold water treatment in private practice. He had succeeded in reducing the temperature to normal, but they had all terminated fatally. Those cases required the most careful supervision. The convulsions were invariably tonic.

Dr. **BROADBENT** said the convulsions took the form of opisthotonos without clonic convulsions.

Dr. **CARRINGTON** said, in reply, that the convulsions came on after the patient had been removed from the bath. The first bath lasted a good hour, as a great difficulty was experienced in reducing the temperature of the bath. He thought the antipyrin did more harm than good by favouring collapse. The salicylate did not appear to have had much effect either. He thought antipyrin was a dangerous drug.

EPILEPSY AFTER GUN-SHOT WOUND.

Dr. **HADDEN** brought forward the case of a man, æt. 32, who was under Mr. Croft's care at St. Thomas's Hospital There was no family history of epilepsy. In 1872 he was wounded in the left calf, and several shots were extracted. In six or seven weeks the wound was quite healed. Four months after the injury he began to have fits. For nine months they were occasional, but afterwards he had as many as twelve daily. The sciatic nerve was then stretched, and the fits ceased for thirteen years. They recommenced seven weeks before admission into St. Thomas's, when he fell to the ground from a ladder unconscious. During the week preceding admission he had eight or ten daily. The fits began with a sharp twitching pain in the scar in the left calf; then there was a creeping, heating sensation passing up the leg and left side of the body to the head. The left side then became convulsed. The pupils were immobile, and the conjunctivæ insensitive. Finally, there were some general convulsive movements, and then rapid return to consciousness. The tongue was not bitten, nor were the evacuations passed. The scar was somewhat tender, and when pressed he would at times have the sensation passing up the body, and sometimes a convulsion. Occasionally in the seizures he would roll about in bed, and sometimes there was opisthotonos. An attempt was made to stretch the sciatic nerve by extreme flexion of the hip, but the result was a violent convulsion. A few days later the nerve was exposed and freely stretched. The fits stopped for nine days. He then had occasional seizures, sometimes one a day, sometimes one every other day. Two occurred whilst the splint was being bandaged to the leg, and one during removal of the splint. The man wrote four months later to say that he had had no convulsion since he left the hospital, but he suffered from severe paroxysmal pain in the left calf, followed by the "fitty" sensations. There was no doubt that the attacks were genuine, the condition of the pupils and conjunctivæ and other points proving this. The interest of the case has reference to Brown-Séquard's and Victor Horsley's experiments on guinea-pigs. Epilepsy was induced by these observers after injury to the sciatic nerve. There is usually a latent period of from two to six weeks. In the man the incubation was four months. Opisthotonos occurred in the patient, as in the case of guinea-pigs.

Mr. **BOWLBY** said he remembered a case at St. Bartholomew's Hospital where a man had a gunshot wound of the leg, which was followed by epileptic fits. The musculo-cutaneous nerve was resected first, and this procured an immunity from the fits for five years. They then recurred and some shots were removed from beneath the skin, and this operation was followed by another remission. Some months later, the fits recurring, the sciatic nerve was stretched, and since that time no more fits had been observed.

Dr. **CARRINGTON** said that possibly the operations may have had somewhat the same effect as the old-fashioned setons which were formerly a recognised method of treating epilepsy.

Dr. **ANGEL MONEY** said the occurrence of epileptic fits at particular periods had never been satisfactorily explained. He knew a man who could induce an epileptic seizure by eating chocolate, and suggested that an irritated stomach might play the same *rôle* as a seat of injury.

HÆMATURIA AND GRANULAR KIDNEY.

Mr. **ANTHONY BOWLBY** read a paper containing the records of three cases of hæmaturia in connection with granular kidney. The first is that of a man, æt. 73, who was admitted into St. Bartholomew's, suffering from enlargement of the prostate and hæmaturia. His death, which occurred within twenty-four hours, appeared to be chiefly due to the exhaustion caused by the loss of blood. A post-mortem examination showed an enlarged prostate and dilated bladder, containing several ounces of almost pure blood. The kidneys were small and granular. Their pelves and the ureters contained blood, and in the renal substance there was much blood extravasated. Microscopical examination showed that the hæmorrhage had occurred both into the renal tubes and into the cellular tissue of the gland. The second case is that of a man, æt. 49, who had long suffered from stricture of the urethra, and difficult micturition, and who for three months previous to admission into St. Bartholomew's Hospital, had passed considerable quantities of blood with his urine. He had many of the ordinary signs of interstitial nephritis, and, in addition, passed a great deal of blood. On his death from uræmia no cause of hæmorrhage was found, except in the kidneys. These were small and granular, and contained a little bloody urine. In the third case, a man, æt. 64, was admitted on February 3rd, 1886, with profuse hæmaturia, and pain in the loins. After losing much blood for several weeks, the hæmaturia ceased. The urine when clear contained albumen. There was some albuminuric retinitis and some opacity of one lens. Attention is drawn to the fact that the subject of hæmaturia in connection with granular kidney has received little attention, and that no cases of profuse hæmaturia of this nature have been previously recorded, and that no post-mortem examinations have been described. It is pointed out that in one of the patients who are the subject of this paper the hæmorrhage was so profuse as to be mistaken for vesical bleeding, and in the others, the diagnosis had to be made from other of the more recognised causes of renal hæmorrhage, especially calculus. It is in connection with this question of diagnosis that these cases are of importance. Lastly, it is stated that simple intestinal nephritis, independent of dilation or absorption of the renal substance is often found as the result of obstruction to the outflow of urine.

Dr. **Carrington** said that these cases were very rare, and suggested that the instruments might have been responsible for the hæmorrhage.

Dr. **Hadden** quoted a similar case in which, at the *post-mortem*, hæmorrhages were found in the substance of the kidney.

Dr. **Maguire** did not think that hæmorrhage in cases of granular kidney were as rare as stated. Patients sometimes seemed better after slight hæmorrhages.

Dr. **Broadbent** said that severe hæmorrhages were doubtless rare. He had seen a case where the patient bled to death in spite of treatment.

Dr. **Arthur Davies** showed two living cases of myxœdema (male and female).

◆

LIVERPOOL MEDICAL INSTITUTION.

The eighth ordinary meeting of the Session was held on Feb. 3rd, 1887.

The President, Dr. **Nevins**, in the chair.

SKULL THREE YEARS AFTER TREPHINING.

Dr. **Alexander** showed a calvarium which he had trephined three years before for left hemiplegia, intermittent attacks of coma, and increasing imbecility, taken from a youth, æt. 18, who was subject to occasional but rare epileptic attacks. The trephine opening, three-quarters of an inch in diameter, was made over the right parietal convolutions through an enormously thickened skull. The membranes were found to be healthy, but a considerable amount of œdema was apparent beneath the dura mater. The dura mater collapsed when the circle of bone was removed, and the œdema gradually dispersed. Pieces of bone were grafted in the dura mater, and the wound closed in the usual way, the whole operation being performed under strict antiseptic precautions. Union by the first intention took place, and much benefit resulted, lasting for two years. The patient could walk about with the aid of a stick, could look after his interests, and the paralysis almost disappeared. Then the old symptoms returned, complicated during the past six months by urinary troubles, diagnosed generally as those produced by cystitis, under which the patient sank. He had, however, only one or two epileptic attacks since the operation. The calvarium now exhibited a *small* aperture at the site of trephining, large enough to admit a No. 2 English catheter. Through this a small vein passed in the recent state. The whole skull was enormously thickened, and the new bone had become so connected with the old that no one unacquainted with the history of the case would suspect that trephining had ever been performed. The brain was much atrophied, its convolutions covered by clear effusion, but no evidence of any coarse lesion was found, except that it seemed firmer to the feel than usual. All the other organs were practically speaking healthy, except the bladder which was contracted and inflamed. The left ureter seemed much constricted at either end, but a No. 1 English catheter could pass through both constrictions. The renal end was closed by a valvular arrangement that probably prevented the discharge of the thin purulent contents of the large sac into which the kidney had converted. No renal substance remained. The opposite kidney was enlarged and healthy. The urethra was patent, and always had been patent.

EXTENSIVE ULCERATIVE ENDO-ARTERITIS WITH OBSCURE SYMPTOMS.

Dr. **Alexander** showed the heart and aorta taken from a tailor, æt. 67, single, of doubtful habits, who was admitted into hospital, suffering from debility and rheumatism. His appetite was good, and had been so always, temperature normal, and there are no events to chronicle in the previous history, except that he had gradually been failing in health and strength for some time. No evidence of syphilis or hereditary disease. The most prominent symptoms, however, was the startling whiteness of the man, catching at once the attention of the observer, standing out in relief even against the sheets of his bed. His lips were very white, and the tongue pale. The hair of the head and face was quite white, but this is often seen at his age. He complained of a little pain at the epigastrium, and of some tenderness on pressure, but altogether he had very little discomfort beyond that arising from a feeling of great and persistent weakness. His face was always placid and pleasant, and he never grumbled through all his illness. Loud anæmic murmurs prevailed along all the blood-vessels and abdominal pulsation was very distinct, and diffused in the aorta. There was no rough cardiac murmur, but a very loud anæmic one. The pulse was 90-100, and very small and weak, and the patient was confined to his bed through debility. He gradually sank, and died on Jan. 7th, 1887, exhibiting no further symptoms, nor complaining of anything more than still increasing weakness. He never got up after admission to hospital. A post-mortem showed general dilatation of the aortic arch, and of the upper two-thirds of the thoracic aorta. With this dilatation the arterial wall showed various stages of disease, viz., atheromatous patches; ulcerated areas covered with tufts and layers of old standing and partially organised fibrine; cicatricial areas, one of which was an inch in diameter, where the inner coat seemed to have entirely disappeared, and a loose cicatricial tissue to supply its place and aneurismal areas, where several pouches of varying depth were seen. From the lower part of this affected area to just beyond the cœliac axis the vessel was comparatively sound and undilated. Beyond the cœliac axis the vessel became again dilated. This dilatation was about three times the normal diameter of the vessel, and was filled with a large mass containing clots of different kinds. Nearest the walls of the vessel firm, adherent, tufted masses of fibrine were seen enclosing in the centre of the vessel a white brittle, grumous-looking clot. The dilatation and clot extended to the termination of the aorta, but did not affect the iliac vessels which were free. On lifting off, or rather on tearing off the fibrine from the posterior wall of the vessel it was found that the coats of the vessel beneath were entirely changed. A mass of cheesy material (ulceration products) lay behind this constituting a diffused flattened abscess that covered the bodies of the vertebræ. At one spot this abscess had extended through the anterior common ligament, and had penetrated the body of the vertebra behind for a quarter of an inch.

Dr. **Alexander** also showed the Lower Portion of Rectum removed by a New Method for Malignant Disease.

Dr. **Robertson** showed a case of Congenital Malformation of Heart and Renal Disease; the malformation consisting of patency of the upper part of the ventricular septum.

FIBROID DEGENERATION OF HEART AND ANEURISM OF LEFT VENTRICLE.

Dr. **Glynn** exhibited a heart which presented the following interesting lesions:—The apex was, externally, rounded into a distinct swelling, and very fatty. On opening the ventricles the apex of each was found to be the seat of an aneurismal dilatation, that of the left being very defined and large, capable of holding a walnut. The walls of the aneurism were no thicker than thin cardboard, and were formed on the inner side of straw-coloured fibroid tissue, distinctly reticulated like the normal heart in this situation. On the outer side the wall was formed of loose fatty tissue, and presented no appearance of muscle in any part. The wall of the right ventricle and the ventricular septum was also the seat of extensive fibroid change; the pale degenerated area extended upwards from the aneurism to the pulmonary valves, and laterally it extended across the septum and anterior ventricular wall for about four inches. The affected parts were so wasted as to transmit light. All the cavities of the heart were dilated, especially those on the right side. The sigmoid valves were healthy, but the auriculo-ventricular valves were incompetent, owing to the dilatation of their respective orifices. The patient, a middle-aged female, was admitted under Dr. Glynn's care into the Royal Infirmary suffering from dyspnœa, dropsy, and palpitation. She gradually became exhausted, and died, after being under observation about three months. She had never had rheumatism, but had suffered on two occasions from typhus fever. It was quite possible that the local degenerations of the heart's walls were the result of a myomalacia cordis occurring during the typhus fever. On physical examination it was found that the heart was much enlarged, The apex beat was in the sixth space, 7½ inches from the mesial line, and there was a diffused impulse all over the præcordium and in the epigastrium. On auscultation little evidence of valvular trouble was found. There was only an occasional systolic murmur at the apex. The rhythm of the heart was unusually peculiar; two ventricular systoles occurred together, and were followed by a long pause; cardiographic tracings exhibited two waves close together, the first of fair height, with vertical upstroke, but pointed summit, the second much lower, with oblique upstroke and rounded summit. Simultaneous cardiographic and sphygmographic tracings showed that the first systole was immediately succeeded by a pulse wave of fair magnitude, while the second systole only caused a slight oscillation in the line of descent of the previous pulse wave. Eighty cardiac revolutions occurred to forty radial pulse waves appreciable by the finger. On auscultation there was reduplication of the first sound everywhere over the heart; the second sound was also often reduplicated, and was only audible at the base, the second sound, or the reduplicated second sound, was only heard after the ineffectual systole. From the evidence furnished by the tracings and by auscultation it appeared that the action of the ventricles was not quite synchronous, and that possibly in systole there were two distinct contractile efforts, and that between these the sigmoid valves did not close. Coloured drawings of the heart were exhibited, and also of a heart from another case, where in a young man extreme general fatty degeneration of the heart was associated with obstructed coronary arteries.

Dr. Glynn also exhibited a specimen of Aneurism of the Aorta pressing on the Right Bronchus. The case was interesting as the more direct signs of aneurism were absent, and general emphysema and caseous degeneration of the right lung had been excited. The diagnosis of the case depended on the absence of vocal fremitus and the feeble breathing over the right lung.

Mr. G. Hamilton for Mr. Puzey read notes of a case of Recurrence of Disease in Stump after Amputation for Sarcoma of Tibia.

Mr. Damer Harrisson read a paper on

THE TREATMENT OF FRACTURES OF THE SPINE AND TRAUMATIC PARAPLEGIA BY A NEW SPLINT AND ANTISEPTIC DRAINAGE OF THE BLADDER.

The paper was founded on ten cases of fracture of the spine treated by him in the Northern Hospital in which the method of treatment had been that now described. The splint was one devised by himself by means of which the fractured ends were brought into apposition with a greater degree of accuracy than could be secured by any other form in use, arrangements being made for the flexion of any part of the spinal column required, and of the thighs upon the trunk. Great stress was also laid in the paper on thorough aseptic drainage of the bladder through the perinæum from the commencement of the treatment. [We hope to give this paper in full with illustrations later on.]

Mr. Reginald Harrison said that he considered the paper of much interest as it dealt with the two most important points connected with this fatal kind of injury. He had long felt that in the treatment of fractures of the spine more might be done by surgeons in reducing displacements with as little delay as possible, and in maintaining the fractured portions in correct apposition by some such apparatus as had been shown this evening. He mentioned the case of a woman who had been admitted into the Royal Infirmary under his care with a fractured spine in the lower dorsal region with complete paralysis of motion and sensation below this point. Twenty-four hours after the injury extension was applied to the spinal column, under an anæsthetic, and the displaced portions were distinctly felt to fall into something like their natural positions. The patient was placed on a suitable mattress with sand bags, and some extension by pulleys was kept up. Within twenty-four hours after reduction both motion and sensation returned in the paralysed parts, and the patient made a complete recovery. Had extension and manipulation not been resorted to this patient would either have died or become permanently paralysed. He (Mr. Harrison) thought that in some instances the practice recommended of draining the bladder continuously by a perinæal incision might be adopted with advantage. The constant use of the catheter, and the undrained condition of the bladder contributed in many instances towards a fatal termination. Whether, as had been suggested, this unhealthy state of the bladder also contributed towards rendering the paralysis permanent as a reflex source of irritation, in those cases where repair of the fracture itself did take place, he had some doubt. He thought the practice of draining the bladder under these circumstances, as illustrated by the author of the paper, a good one, and worthy of imitation.

Mr. Harrisson then replied.

WEDNESDAY, MARCH 2, 1887.

THE DEFECTS OF MEDICAL TRAINING.

At the last meeting of the General Medical Council, Dr. Glover made a very telling speech on the shortcomings of our present system of medical education and examination. He alluded to the incapacity of the newly-qualified man for general practice, and ascribed it to the want of education in practical subjects, and especially of that class of work which falls to the lot of the general practitioner. The remedy for this state of things was, in his opinion, to exact a *stage* with a registered practitioner, where the young doctor would have an opportunity of becoming familiar with the routine of daily professional work. It is an indisputable fact that after the regulation course of study at a medical school and hospital, several very important branches of professional knowledge may be *terra incognita* to the student or young practitioner. He may never have seen a broken limb before it is artistically swathed in bandages by the house-surgeon, still less have had an opportunity of manipulating it, and so learning to recognise the *crepitus* and other indications of fracture. The chances are a hundred to one that he has never seen a case of measles, scarlet fever, or small-pox, and this *lapsus* is far more important in its results than ignorance on surgical matters. What will his patients think of him if they detect a trace of hesitation when he is called upon to diagnose between scarlet fever and measles; what will be the result if he declares a case of varioloid to be chicken pox? We have heard of frequent cases in which small-pox was diagnosed as measles until the mistake stared the man in the face. Residents in fever hospitals could tell a pitiful tale of errors of diagnosis in the cases sent to them for treatment, some of them so flagrant that it is difficult to conceive of their having been made by men nominally conversant with the duties of their calling.

In obstetrics the lack of practical training is quite as apparent. In Scotland only six attendances on labours are required of the student, and, as Dr. Glover very appositely remarked, the position of the man who stumbles on a case of arm presentation or post-partum hæmorrhage for Case No. 7, is easier to imagine than to describe. As a matter of fact, even in London, where twenty attendances are required, practical instruction in obstetrics is simply non-existent. What is a man likely to learn from attending twenty uncomplicated confinements without any technical instruction therein or upon. He will learn, it is true, how to make an examination, and possibly to ascertain where the *os uteri* is and what it feels like—details of some importance, but so far as the operative details are concerned he will be very little better off than the old woman whom he finds in charge of the case. Steps ought certainly to be taken to remedy this condition of things. Either the student should be admitted and compelled to attend labours in one or other of the workhouses or lying-in hospitals which abound, or an obstetrical ward should be created in general hospitals. Both plans have long been in operation abroad with the best results. In Dublin and certain other towns special facilities exist for the study of gynæcology and obstetrics, but in London even the diligent student can do little or nothing.

It is on this account that, on the one hand, the practitioner hesitates to confide his patients to a newly-qualified assistant, and, on the other, that newly-qualified men find it indispensable to perfect and complete their education by passing a year or two in a subordinate capacity, in order to acquire, at the expense, it may be, of his patients, what his medical training had failed to teach him.

It would probably be an unmixed advantage to insist on men completing their studies in actual practice. They would there learn to dispense neatly and correctly; they would be enabled to divest themselves of the manners which, if admitted in hospital practice, are not favourably received elsewhere, and opportunities would occur to cultivate an acquaintance with diseases which they had not hitherto met with, and, above all, with the treatment of that large class of cases which, as Sir Wm. Gull observed, have no morbid anatomy, viz., ailments. Accurate and exact diagnosis is always a desideratum, but this is not always possible, for the simple reason that there may be nothing to diagnose. The first few months of general practice gives a man, fresh from the schools, the sensation of walking in the dark, from his inability to refer his cases to their proper nosological position. By-and-by his eyes become accustomed to the obscurity, and he acquires the art of jogging along the beaten path undisturbed by qualms as to eventualities and possibilities. Of course the great art is to treat ailments as ailments, and to distinguish between these and definite diseases. Woe betide the man, however, who, having got used to the twilight, keeps his eyes shut. He will treat typhoid fever for diarrhœa, and intestinal obstruction for constipation, and his last state will be worst than the first.

The *quasi* apprenticeship to a medical man, which is still allowed to take the place of part of the curriculum, would possibly be more advantageously insisted upon as the termination of his studies instead of the beginning. The only drawback is that a man who has just succeeded in proving his knowledge of medicine, surgery, and midwifery to the satisfaction of this or that examining board, will, in all probability, prove a less docile pupil than the aspirant student. He will be apt to "fancy" himself and despise the drudgery of daily toil, where rule-of-thumb takes the place of scientific research. It must not be forgotten, however, that medicine for most men is a means of gaining a livelihood, and if it is to prove successful as such, the minor details of the art and practice of medicine are at least equal in importance to the higher and more absorbing departments.

◆

SAFEGUARDS OF THE IMPARTIALITY OF EXAMINATIONS.

We learn with surprise and regret that the Fellows of the Irish College of Physicians have insisted on introducing into the Conjoint Examination Scheme for Ireland a proviso which strikes directly and strongly against the impartiality of the examinations of the future, and undoubtedly will operate as an inducement to personal jobbery and earwigging of which such tests should not be even remotely suspected. Heretofore each student has been enrolled in the Registrar's books of the College of Surgeons by a number, and has been known to the examiners only by that number, his personality being entirely unrecognised by them. Under this numerical *soubriquet* he has been dealt with exactly as his answering seemed to deserve. He was not favoured for the sake of his family, helped because he happened to be the apprentice of a friend, or prejudiced because he came from a particular school, or because he had been previously rejected. If any one of the examiners happened to have personal acquaintance of him that knowledge did not extend to the rest of the Court, and, therefore, could not materially improve or prejudice his chance of passing, even supposing that the examiner were to show bias in his marking. We speak not only of the probable effect upon the examination of the system of indication by numbers, but of its actual result, for the examinations of the College of Surgeons, whatever they may have been as practical tests of competency, are admitted by students and grinders to have been singularly free from partiality or unfairness, and the best proof of this is that the near relatives of those who are high in collegiate influence have been, on several occasions, rejected, either because of the strict justness of the examiners, or because of the *incognito* of the student. Moreover, the system of numerical indication has been a great relief to the examiners, because it protected them from the attempt to influence them in favour of the candidate. Such attempts are common to all examinations, and are made by unprincipled people without conscience or shame; so much is this the case that the preliminary examiners at the College of Surgeons, finding themselves unblushingly importuned by the friends and relatives of candidates, petitioned the College not long since to allow the candidates for that examination also to be indicated by numbers, and the request was at once agreed to. Under the numerical system, the examiner who has not the strength of mind to return an angry No! to such an insult to his honour is armed with the ready reply that he cannot—if ever so willing—help the candidate, because he will not be able to recognise him. But, even if these precautions were illusory, they ought, we think, to be by no means abrogated, inasmuch as they give confidence to the student that he will be fairly dealt with upon his answering. For these obvious reasons, we repeat, it surprises us to find the Fellows of the College of Physicians proposing to revert to the old system, under which personal jobbery was easy, and, in fact, not uncommon; and we very much regret that the Council of the College of Surgeons in its hot haste to complete its Conjoint Examination Treaty, conceded this, with many other moot-points, to the College of Physicians. We of course anticipate the serenely virtuous air with which the promoters of this retrogressive change in the College of Physicians will assure us that *their* examiners are loftily superior to personal influences, and that it is an insult to them to suggest that their virtue needs to be guarded by any such system as numerical indication. We beg to say that we entertain no more suspicion of their Rhadamanthine strictures than of the honour of any other court of examiners in or out of the profession; but they and their co-examiners of other Colleges are but men, and without speculating upon what might be, it is notorious that, under the old system personal jobbery was rife, as it will be again if the College of Physicians has its way. It is not to be supposed that the change is made with a view to such end, but we entertain no doubt that it will have such effect, and we very much wish that common sense and practical experience were allowed their proper influence in such a matter rather than the stilted *amour propre* which seems to guide the Irish College of Physicians in the affairs of life.

◆

In a football match last week between Balliol and New College under Rugby rules, in the Parks, Oxford, Mr. Victor Morier, an undergraduate of Balliol, was severely injured and was removed from the ground in an unconscious condition. He was taken to his College, where medical assistance was obtained, and he was found to be suffering from concussion of the brain. Late in the evening consciousness returned. He is the son of Sir Robert Morier, Ambassador at St. Petersburg.

Notes on Current Topics.

Noisy Nuisances.

The susceptibility to noise varies greatly in different individuals, while one person can work or sleep undisturbed by the clamour of children, or the melancholy growl of the hurdy gurdy, others are so constituted that sound of any kind except the most subdued of murmurs, has the property of exciting and irritating their nervous system to such an extent as to incapacitate them for either work or idleness. By an unfortunate physiological law, it is precisely the hard worked denizen of large cities, and more particularly those who from the very nature of their occupations, require either quiet or an indifference to their surroundings, who are generally least able to put up with the multitudinous noises which are more or less inevitable in cities. With many this irritability is only a symptom of unsettled nervous equilibrium due to faulty arrangements in the matter of food, work, or habits, but in others, probably of hereditary origin, it exists *à l'état normal.* A great many noises are, as we have said, inseparable from life in crowded centres, but unfortunately there are a great many which can and ought to be separated. A dog which is addicted to baying the moon, a cock prone to boast of his marital achievements or a licentious cat, are sources of annoyance even to the most placid and lethargic people, and are happily amenable to laws for that purpose made and provided. It is distressing to be obliged to constrain one's neighbour to remove or silence his pet animals, but still it can and often is done. There are other sources of noise, quite as unnecessary as the preceding, but less easy to put a stop to. A good example of this class of nuisance is the whistle of the locomotive and the fog-signal. Both are employed to an extent quite out of proportion to the necessity, and it would not materially interfere with traffic, were these noisy methods of communication replaced by less clumsy and less irritating contrivances. A railway company is not a nice party to haul before a magistrate, and, vain of their impunity, they refuse to the unhappy persons who dwell in the vicinity of their lines, the opportunity of listening to what the wild waves are saying. In a town like London where it is difficult to get out of reach of a railway the nuisance is a formidable one, and one which demands some interference with the autocrats of the steam traffic. There is no reason why, if locomotives are permitted to warble thus, tramcars and omnibuses should not also utter a shrill screech at each move, but means would soon be found to stop them if they did so. There is ample scope for a society which should undertake the suppression of nuisances of this description. It is certain that there is plenty of work for such a body, and if properly organised it would be the means of doing great public service. It might be called the "Jubilee Nuisance Prevention Society."

M. Eugene Rimmel died unexpectedly on Friday evening. He was in his 67th year. In conjunction with Dr. Vintras and one or two French residents in London, he founded the French Hospital and Dispensary.

Magnetic Humbugs.

It is difficult to refrain from a feeling of indignation on meeting, in the columns of generally respectable journals, with the advertisements under the guise of editorial matter of those arch quacks the "magnetisers." This genus endeavours to palm off upon a gullible public bits of magnetised steel sewn up in waist bands, chest protectors, or what not at an exorbitant price, under pretext of working all kinds of marvels in the treatment of curable and incurable affections. The specious statements and artful tricks of these gentleman are amusing to read and entertaining to witness, and it is really no matter for surprise if the public succumb to the wiles of people who know their weak points and carefully tickle them. Like many other varieties of the genus quack, they flourish in the advertising columns—and even elsewhere—of the religious journals, among the readers of which, it is to be supposed, they drive their trade. Justice requires us to admit, however, that their pseudo-remedies are at any rate fairly innocent in their nature and do not contribute to the mortality for which the soothing syrups and teething powders are to a large extent responsible.

Presentation to Sir Henry Acland.

The graceful ceremony of presenting the President of the General Medical Council with a bust of himself, which took place on Monday, Feb. 21st, was a fitting acknowledgment of many years of useful and not always agreeable labour. It was the more opportune seeing that Sir Henry anticipates being obliged at no distant date to resign the presidency, but with a tact and judgment which testifies to the interest he takes in the question of medical education, he intimated his intention of holding office until the next meeting in order to facilitate the settlement of the difficult questions in connection with the conjoint scheme.

A Ray of Hope.

The decision of the General Medical Council to refer the matter of the exclusion of the Apothecaries' Societies in England and Ireland back to the Royal Colleges in both countries for their further consideration, coupled with an intimation that the request was made by the Council in the interests of the profession, opens up the possibility of a serious reconsideration of the present position of affairs. As Sir Dyce Duckworth admitted, the demand for admission on the part of the Apothecaries' Societies was refused on practical grounds, as neither necessary nor desirable. If the Colleges were appealed to, however, "in the interests of the public and of the profession," it was possible that another view might be taken of the matter. We sincerely hope that on a question of this importance the interests of class may not be allowed to inflict an irreparable damage on the cause of medical examination and status. If the Colleges would waive the question of principle, and consent to discuss the demand of the Apothecaries' Societies, the onus of proving that they had been unable to obtain admission to the conjoint board on "fair and reasonable terms" would be thrown on to the Apothecaries' Societies, who have everything to gain from a refusal of their demands. The more exalted the position of the Colleges, the more incumbent it is upon them to avoid any appearance of indifference to the grand interests of which they are, to a large extent, the custodians.

A Want of Consistency.

It is always a disagreeable task to have to criticise the conduct of a contemporary, but when the difference between precepts and practice becomes too crying a scandal, the task is one which can hardly be avoided. In the advertising columns of the *Lancet*, for last Saturday we find the following advertisement:—

> YOUNG GENTLEMAN (married), sine diploma, but with considerable experience in General Practice and in Midwifery, wishes to meet with a qualified gentleman who would be willing to accept him as Junior Partner, where his practical services and capital would be useful and appreciated, &c.

It is scarcely necessary to point out that the combination suggested is one which is justly regarded as one of the grossest breaches of professional etiquette; it is one moreover which would promptly subject the "qualified gentleman" to the penalty of having his licence to practice withdrawn. The unholy alliance thus set forth is one unfortunately which is far too common, but it is singularly and peculiarly unbecoming that a journal which professes to dictate in matters of professional etiquette, should deliberately and wilfully aid and abet any such transaction. We say deliberately, because it is by no means the first time that the journal in question has sinned in this way. The only explanation of such an extraordinary contradiction between what they profess and what they practice, is that considerations of a financial character are allowed to decide what really should be looked at from a far higher standpoint. Without wishing to appear to "damn the sins we're not inclined to," we may fairly claim to have acted up to our principles in this matter by consistently refusing all advertisements for or from unqualified men.

Iodoform on Trial.

Since the introduction into surgery of iodoform as a dressing for wounds, doubts have from time to time been expressed respecting the reality of the benefits presumed to be associated with its use; and indictments against it have been framed by more than one observer convinced that his own experience has contraindicated its employment. It is only quite recently, however, that the antiseptic properties of the drug have been impugned, though instances of supposed poisoning due to its absorption have not rarely been reported. The occurrence of eruptions following its use, too, has lately been a subject of discussion, especially amongst American surgeons, the New York Academy of Medicine having very lately been engaged in the consideration of a paper bearing on the question. In this communication the author, Dr. R. W. Taylor, arrived at the conclusions—1. That a mild erythema, particularly of the fingers and about cuts, was produced in those, hospital assistants, &c., who used iodoform freely. The eruption caused little or no distress, and ceased on discontinuing manipulation of the drug. 2. Open granulating wounds dressed with iodoform might sooner or later become the seat of a simple, superficial erythema, or of considerable œdema, and in either case papulation, vesication, pustulation, or even phlegmon might ensue. 3. That in those persons possessing what may be termed an iodoform idiosyncrasy, application of the agent to the throat, or to the nose by smelling it, is apt to produce, as the result of its absorption, severe skin affection of the face, head, hands, feet, &c. This latter observation recalls the similar effects of idiosyncrasy in connection with various other drugs, *e.g.*, potassium iodide and bromide, ipecacuanha, &c, and it is not improbable that individual characteristics may be the dominating influence in producing the iodoform rash as much as they are recognised to be in the other cases referred to. This is the more probable from the fact that all persons do not suffer alike when submitted to the same exciting cause; while some are deeply affected, others may be entirely uninfluenced; but it is useful information that enable us to extend the list of those remedies which are capable of producing results against which we ought at any rate to be fairly on guard. Iodoform clearly ranks in this list, and should the suggestions as to its uselessness from an antiseptic point of view prove to be well founded, two sufficient reasons will be present for warranting a serious inquiry into its title to hold a place any longer in practical surgery.

A Hard Nut.

The champion correspondent of the anti-vaccinationists, Mr. William Tebb, has devised a most ingenious method for extending the area over which his propagandist efforts are distributed. He has hit upon the brilliant notion of addressing his lucubrations to the American people, and the medium selected for his first attempts in this direction is, *mirabile dictu*, the New York *Medical Record*. Faithfully reading the mental characteristics of his newly discovered audience, however, Mr. Tebb treats them to a series of views in medicine as attractive as they are startling, the major proposition contained in the letter we are referring to being that the growth in the mortality from *cancer* is due to vaccination. The unsuspecting American readers of his epistle are then asked to accept the statement that "some medical men" attribute this increase in cancer "to the large amount of syphilitic disease with which vaccine lymph is impregnated." Then, as "some medical men" might be held, even by Transatlantic intelligences, to be a somewhat vague term, the authority of a Dr. William Forbes Laurie is quoted in support of Mr. Tebb's pleasing fiction. This gentleman, Dr. Laurie, was, it appears from Mr. Tebb's letter, formerly "Medical Director of St. Saviour's Cancer Hospital, Regent's Park," and doubtless he serves as well as another to fulfil the end aimed at by the anti-vaccination *littérateur*. Mr. Tebb modestly invites American physicians to devote their clinical labours to proof of his suggestion, and we shall be much amused to see the effect produced by the successful and masterly move to which our esteemed contemporary has somewhat unconsciously lent itself as an aid.

Orders have been given at Aldershot for the Royal Artillery schools to be temporarily closed on account of a visitation of measles.

A Medical Co-Respondent.

Dr. Brown is to be congratulated on the verdict which exonerated him from immoral and unprofessional conduct in the suit Lennard *v.* Lennard. This gentleman's conduct throughout the affair was marked by the strictest propriety, both in his professional and social relations. Not only did the jury find him not guilty of adultery, but the judge added some very sensible remarks on the evil consequences of such charges against medical men, and said that this charge in particular ought never to have been brought: The hardship and expense of having had to defend himself still entitles Dr. Brown to our sympathy. It is high time the profession banded together to defend the reputation and prospects of their members when unjustly assailed.

The Right to Advertise.

An application has been made to the Queen's Bench Division for an order to compel the General Medical Council and their Registrar to re-instate the name of a dentist whose diploma has been withdrawn by the Royal College of Surgeons of Ireland two years ago for advertising contrary to their regulations. The application was based on the fact that advertising was not specified in the Dentists' Act as a disqualifying action. The attempt is a bold one, and very naturally excites a good deal of interest and comment. As the case is *sub judice* we abstain from expressing any opinion thereon. We sincerely trust nevertheless that no victory on technical grounds will have for effect to remove the wholesome restrictions which at present tend to check a practice derogatory to the dignity and status of the profession.

The College of Surgeons and the Fellows and Members.

The last act of the Council of the Royal College of Surgeons has been to pass a resolution to the effect that, although the Council was not prepared to give effect to the recommendation bearing on the participation of Members in the right of voting and sitting on the Council, it was ready to appoint a committee to confer on the subject with representatives from the two associations. This apparently aimless and contradictory proposition was very properly declined by the association on the ground that "no useful purpose was likely to be served" by a conference on a matter which, so far as the Council is concerned, was already disposed of. The Council of the College will thus be unable to record in their minutes that they have actually condescended to "confer" with representatives from the Associations of Fellows and Members, which was probably their only object in proposing such a thing. Theoretically, it is of course possible that the College might rescind or abrogate its first resolution, refusing the franchise, &c., to the Members, as a result of the conference, but those who are behind the scenes declare that nothing of the kind is in the least degree probable, or to be hoped—at any rate for the time being. Pressure of a more direct and aggressive description will require to be brought to bear on this recalcitrant body before the very fair and equitable demands of the Associations will be acceded to. In dealing with this body, its adversaries require not only the courage of the lion, but the cunning of the serpent.

The English Conjoint Board.

On reference to an official announcement in our advertisement columns, it will be seen that all communications relating to the diplomas of the Royal College of Physicians of London and the Royal College of Surgeons of England, under the old regulations, as well as under those of the new Examining Board, must in future be addressed to the care of Mr. Hallett, at the new Examintion Hall, Victoria Embankment, London, instead of to the College as heretofore.

University of Durham.

The Dean and Chapter of Durham, with the consent of the Bishop of Durham, have enacted a statute constituting the Professor of Medicine of the University of Durham an official member of the Senate of the University, an elective representative on the Senate being continued to the College of Medicine, Newcastle-upon-Tyne. On Wednesday last Dr. Heath was unanimously elected representative of the College of Medicine on the Senate of the University.

Earthquakes.

With regard to the injuries and deaths from surprise, or shock that have been produced by these commotions in the South of France, as well as to their phenomena generally, the following extract from Prof. Huxley's paper, "Scientific and Pseudo-Scientific Realism," in the *Nineteenth Century* for February, will help to remove some of the misconceptions that invest them :—"It is, he says, to say the least, highly probable that this earth is a mass of extremely hot matter, invested by a cooled crust, through which the hot interior still continues to cool, though with extreme slowness. It is no less probable that the faults and dislocations, the foldings and fractures everywhere visible in the stratified crust, its large and slow movements through miles of elevation and depression, and its small and rapid movements which give rise to innumerable perceived and unperceived earthquakes which are constantly occurring, are due to the shrinkage of the crust on its cooling and contracting nucleus."

Compulsory Retirement.

At last the attention of the British taxpayer is being drawn to the ever increasing amount which he, in a collective sense, pays yearly for what are called "non-effective services" connected with the army; and he is becoming aware, moreover, that a large number of officers who have of late been cast upon that list against their own wishes, are, for purposes of work, in the very flower of their manhood, fully able physically for duty anywhere, abroad or at home, and eager to continue on the active list. With regard to battalion officers, this system of compulsory retirement has already, to a small extent, brought about its own remedy by reason of the magnitude of palpable defects connected therewith, and the increase which it occasioned in the army estimates; to a certain extent, therefore, retirements of that kind re suspended, and being so, there is reason to believe, they will not again be enforced. But no similar order of suspension appears to have reached the medical department, and so in their case the taxpayers have still the luxury of contributing to the maintenance in retirement of many officers who are both able and willing to remain on active duty, at the same time that other officers draw full pay for doing those very duties which the men displaced are to a certain extent remunerated for not doing. The plea adduced in support of such a system is that it accelerates promotion among the junior grades. If this be so at all, it seems to hold good only to a small extent; nor is it easy to see in what respect the general interests of the service at large benefit by a system which is expensive beyond any other that has ever been devised. In these days of depression in trade and business of every kind, and of reduced incomes to nearly everybody, it is doubly necessary to look to economy, and assuredly economy is not served by the plan of compulsory retirement at present in force.

Brigade Surgeons in India.

Experience has amply shown that the grade of medical officers called brigade surgeon is unsuited for the particular conditions of the army in India. We are therefore not in the least surprised to learn that the officers of that rank find their position so anomalous, and their pay and allowances so inadequate, and out of proportion to their seniority in the service, that they have at last been driven to the somewhat desperate measure of taking combined action with a view to press upon the responsible authorities what they deem to be their legitimate grievances in both these respects, namely: 1. That in India their rank is not recognised; 2. That they are not exempted from the routine duties which usually fall to, and are more properly in the province of, those who are junior in rank, and younger in years; and 3. That they do not receive that amount in the shape of what is called *staff allowances* to which they consider that their length of service, and their duties render them entitled.

Not only are the brigade surgeons in India, as elsewhere, called upon to perform ordinary "executive" medical duty, but they are from time to time called upon to take up the functions pertaining to the administrative officers, so that like the "Mud Majors" of regiments, they are in their particular sphere everything by turns, and nothing long, at least in what brings additional emolument. In fact, the very name "Brigade Surgeon" seems to imply that officers so designated are expected to perform any and every kind of professional duty pertaining not only to the brigade collectively to which they belong, but also towards every individual belonging to it, whenever the necessity arises. Nor must it be forgotten that the men from whom all this is expected are, as a very general rule close upon fifty years of age, some, indeed, considerably over that age. We therefore trust that the authorities of the India Office will give careful attention to their representations, and deal towards these old officers in those terms of liberality which the magnates of Leadenhall in former days loved to exhibit towards the servants of what was rightly named "The Honorable" East India Company.

WE learn that a volume of papers entitled Pilocereus Senilis, by the late Dr. Moxon, of Guy's, will be published next week by Messrs. Sampson Low & Co.

THE patients of the new Jaffray Hospital, Birmingham, were the recipients of a musical treat on Thursday last, when the celebrated *prima* Madame Marie Roze visited the wards, and before leaving kindly sang several songs

◆

At the Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THE whole time of the last meeting of the Royal Medical and Chirurgical Society was occupied over the discussion of a case of rupture of the urinary bladder, which, however, presented several features of marked interest. The communication was made by Mr. Henry Morris, and had reference to a case which first came under treatment at the Middlesex Hospital in 1879. At that time rupture of the bladder had been caused by violence during a pothouse quarrel, and under rest, hot fomentations to the abdomen, and opium, recovery ensued. Seven years later he reapplied at the same hospital, with symptoms of rupture once more present. This time a fatal termination ensued, and *post mortem* the fundus of the bladder was found united with the rectum by a band a quarter of an inch in length. A rupture in this communicated with the bladder, slight pressure on which caused purulent urine to flow into the peritoneal cavity, which contained about fifteen ounces of the fluid. Mr. Morris pointed out that this case afforded conclusive proof that intra-peritoneal rupture of the bladder is an accident which is not necessarily fatal, assuming the composition of the urine to be normal, and that it was unique in so far as it gave indisputable evidence of the appearances resulting some years after recovery of the organ from rupture. The ensuing discussion was maintained at some considerable length, and with a degree of animation which the unusual and important nature of the evidence contained in the paper fairly justified, and derived additional interest from its being devoted also to a criticism of a paper read immediately after Mr. Morris's contribution, by Mr. W. H. Bennett, on a case of extra-peritoneal rupture of the bladder, and in which the author protested against relieving the distended viscus by aspiration, save in a very limited number of instances. When absolute certainty was wanting as to the soundness of the vesical walls, he condemned the practice, attributing to it the production of rupture subsequently, or of oozing of urine. Mr. Bryant supported the views held by Mr. Morris respecting the case narrated by the latter; and he felt himself compelled to defend his reputation against the charge of having written lightly in his text-book of surgery on the subject of aspirating the bladder. He was fully convinced of the serious nature of the proceeding, and cited cases to show the dangers possible in connection with it. Prof. Humphry also supported the remarks of Mr. Bennett as to the dangers of aspiration, Mr. Barwell and Mr. Hulke following in the same strain.

The harmonious succession of agreeing voices was, however, interrupted by Mr. Rivington, who expressed his dissent from the interpretation put upon Mr. Morris's specimen by the committee who had reported on it. He did not believe it represented an example of intra-peritoneal, but of *sub*-peritoneal rupture. He likewise corrected Professor Humphry's statement that the introduction of normal urine into the peritoneal cavity might be innocuous, appealing to experimental research in support. After a few further remarks from Messrs. Heath, Fowler, and Morris, the meeting terminated.

MEDICAL SOCIETY OF LONDON—MONDAY, FEB. 28TH.

MR. LENNOX BROWNE showed a man for whom he had extirpated half the larynx for malignant disease. This is the third operation of the kind which has been performed, and the extremely successful result not only reflects credit on the operator, but is an encouragement to surgeons to adopt this method of treating malignant affections of this organ. The man could speak clearly and distinctly, and had greatly improved in health and strength since the operation. Mr. Lennox Browne also showed a young married woman who had suffered from faucial and pharyngeal tuberculosis. The symptoms was very painful and urgent, deglutition being almost impossible. Microscopic examination showed abundance of tubercle bacilli. Cocaine was applied, and the granulations were thoroughly scraped off; then a solution of lactic acid, gradually increased in strength from 30 to 60 per cent., was applied, and the surface, after a sharp attack of pharyngitis, granulated healthily and the symptoms disappeared.

Dr. Robinson showed a case of excision of the hip-joint in an adult, and Mr. Pickering Pick showed a boy who had been the subject of that curious form of dislocation of the hip after fever which is sometimes met with. Mr. Morgan alluded to a very interesting case of this kind in which he had cut down and examined the condition of the parts. He found the head of the femur on the dorsum of the ilium, the capsule stretched, and the acetabulum full of granulations, so as to render replacement impossible. Mr. Browne showed two cases of ichthyosis hystrix, and Mr. James Black showed a man who, in consequence of severe hectic symptoms pointing to an abscess in the neighbourhood of the ear, had his mastoid process twice punctured, and finally was trephined, and extensive exploration made of the cerebrum, but without any particular result except that the man recovered and was now apparently quite well.

Edinburgh.

[FROM OUR OWN CORRESPONDENT.]

UNIVERSITY OF EDINBURGH.—ACADEMIC HALL.—The arrangements for the erection of the Academic Hall in connection with the University of Edinburgh are so far completed that negotiations have been entered into for the purchase of a site. It is estimated that about £12,000 will be necessary. The Government has been again approached on the subject, with the result that it is expected that £6,000 will be granted. It is further stated that the generous donor of the munificent sum which is to go to the erection of the building has offered an additional £4,000 for this special end. The task of making up the additional £2,000 should be a light one among so wealthy a constituency as those who are interested in the welfare of Edinburgh University.

UNIVERSITY OF EDINBURGH LABORATORIES.—Most encouraging accounts have been received of the work that is in progress in the different laboratories of the University o Edinburgh. The chemical, the materia medica, the pathological and bacteriological, the practice of physic and th public health laboratories, have each their contingent original workers. Already the published reports contain much of scientific importance, and we are informed, on good authority, that there is abundant promise for the future. Never have the laboratories been better equipped with material.

Royal College of Physicians of Edinburgh Laboratory.—It is confidently expected that the establishment of a laboratory in connection with the Royal College of Physicians of Edinburgh will shortly be a *fait accompli.* The site of the building will be in close proximity to the teaching centre. The laboratory will be open to the Fellows and Members of the Royal College, and to others who may be able to comply with certain conditions. It will be under the supervision and direction of a thoroughly qualified biologist, assisted by a well-trained mechanic, whose time will be entirely at the disposal of the institution. The establishment of the laboratory will add fresh stimulus to the spirit of scientific inquiry which has manifested itself in Edinburgh during the last year or two.

Edinburgh Medico-Chirurgical Society.—An important discussion will take place on Wednesday, 2nd March, at the Edinburgh Medico-Chirurgical Society on Cerebral Abscess. We hope to give a *resumé* in our next issue.

The late Dr. Thomas Fraser, Dumfries.—A few days ago the grave closed over the mortal remains of this young but highly gifted physician. Thomas Fraser, M.A., M.B., C.M., died in his twenty-seventh year, at the Crichton Institute, Dumfries, of which asylum he was Assistant Medical Superintendent. After a distinguished course in Arts and Medicine at the University of Edinburgh, he was appointed one of the assistants in the surgical department of the University. Failing health, culminating in the development of diabetes, compelled him to give up his honourable post, and by medical advice he sought for a return of energy in a long sea voyage. He returned to Edinburgh two or three months ago, unhappily not much better. Anxious to continue in harness, he became Assistant Physician to the Dumfries Asylum. But in the midst of his work he fell a victim to a sudden exacerbation of the disease, and he died on the 15th ult. of diabetic coma. Only those who knew him intimately can rightly measure how much of the true and the beautiful and the good has thus been lost to us. His remains were buried in the Grange Cemetery, Edinburgh, in the presence of a large circle of mourning fellow-workers.

Glasgow.

[From our own correspondent.]

University Defenders.—There are few thing more interesting to the initiated than the posing of Drs. (we suppose we must call them Professors) George Buchanan and McCall Anderson as defenders of University rights. Having become possessed of the "coo," they now recognise the value of "prevat property," and disclaim all sympathy with such radical institutions as the one which gave them academic birth. At the annual dinner of the Glasgow University Conservative Club, Dr. George Buchanan, in replying to the toast of "The University," said that "at the present moment they were on the eve of a volcano, at least of something more than evolution; he was afraid of something like a revolution in connection with their ancient University, and it would be for the young men, particularly for the young graduates, to face the subject. It was not for those who were supposed to have feathered their nests—who had got a local habitation and a name in the University—to interfere, because he did not think it likely that any legislative measure would be passed which would destroy any of the vested interests of those who happened to be in their places." This is delightful from one who has not only a vested, but an *in*vested interest in the University, who has feathered his nest, who got a "local habitation and a name" in the University of Glasgow to the tune of £2,500! Dr. McCall Anderson again recently appeared in the Glasgow newspapers as an opponent of the proposed Southern Hospital. Was Dr. McCall Anderson not the founder of the Glasgow Dispensary for Skin Diseases, which became the Glasgow Hospital for Skin Diseases? Did he not become connected with the Western Infirmary through its skin wards by means of money subscribed by the public for the Skin Dispensary in John Street? Has Dr. Duncan and his friends not as good a right as Dr. McCall Anderson to start a hospital and benefit thereby? Is the Western Infirmary not the creation of the medical professors of the University to further their own personal interests? Further, is Dr. McCall Anderson also not a professor through the potency of £2,500? Verily these are interesting defenders of the University faith!

Medical Superstition in the Highlands.—Strange as it may appear to people of intelligence, it is an incontrovertible fact that in the Highlands of Scotland, as in the Continental Highlands, a belief in miracles, and in incantations and superstitious practices of the grossest nature in curing certain forms of disease still exists, of which the following incident, occurring the other day at a village on the west coast of Ross, is an illustration:—A middle-aged fisherman was seized with a somewhat sharp attack of an eruptive disease, popularly known by the name of shingles, which, according to the local wiseacres, could be cured only by an application of blood drawn from a black cat with a knife or other instrument with which the umbilical cord of at least seven male children had been divided, and applied with a feather from the wing of a black domestic hen which had hatched not less than three broods of chickens. To this sanguinary ordeal the patient, at the solicitations of his friends, agreed to submit with becoming resignation and unquestioning faith in its efficacy. Having been undressed and laid on his back with his head towards the south, operator A walked round him three times with the cat, in accordance with the course of the sun. He then held the cat over the patient's breast, while B, with the proper instrument, cropped its right ear, and as the blood trickled on the sufferer's breast, besmeared it over the affected parts with the feather from the black hen, at the same time muttering incantations in the vernacular. Strange to say, the treatment failed to effect a cure, and as the patient is still unwell, he is about to undergo a repetition of the ordeal.

Glasgow Public Dispensary.—The annual meeting of the supporters of this admirable and well-managed institution was held on the 25th ult., Mr. Andrew J. Kirkpatrick presiding. Mr. Robert Meldrum, the secretary, submitted the annual report, which showed the following number of patients treated:—Diseases of the throat and chest, 545; diseases of the skin and ear, 1,230; diseases of the kidney and urinary organs, 343; diseases of women and children, 612—total, 2,730. The income for the year amounted to £229 12s. 3½d., and a balance of £7 10s. 2d. was left in the hands of the treasurer.

Correspondence.

VACCINIA AND VARIOLA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—My attention has been directed to the letter of M.D. in your impression of February 2nd, and that of Mr. Harris, on February 9th, on the identity of cow-pox and small-pox. I have nothing to reply to these letters more than I have already stated with regard to my present belief in the non-identity of the two maladies; nothing your two correspondents have said affords any proof to the contrary, in my opinion. We do not require hypotheses to decide such a question, but an experimental demonstration. If the two maladies are really the same, there should be no difficulty in demonstrating the fact; but commissions composed of most competent men have failed to obtain this proof. There is no difficulty whatever in communicating cow-pox from bovine to bovine, or to mankind, and it ever remains cow-pox. Can your correspondents give me an instance of cow-pox becoming small-pox? I know of no such occurrence. If it only modified small-pox, surely on being carried back to its original soil it would, at least in the course of time, become small-pox. The virus of rabies, fowl-cholera, anthrax, symptomatic anthrax, &c., however much it may be modified or attenuated, is still the virus of these diseases and no other, *i.e.*, it never loses its identity, but will always, under certain conditions, resume its original potency, and again produce its characteristic effects. Sheep-pox is identical with small-pox, so far as symptoms, infectiousness, mortality, and pathological anatomy are concerned; yet this disease has never been converted into cow-pox, though it should be as capable of this conversion as the human disorder. I would gladly assist in the carrying out of experiments instituted with the view of settling the question; though I apprehend that, when it is remembered that Ceely and Klein, acting conjointly, failed in converting variola into vaccinia, though enjoying every advantage, there is little if any prospect of others succeeding. However, I think the time has long since arrived when the question should be set at rest, for it is not creditable that grave doubts should still be entertained with regard to a subject which is of such immense importance to mankind.

I am,
Yours truly,
War Office,
Pall Mall, Feb. 23rd.
George Fleming.

◆

INTRA-PERITONEAL HÆMATOCELE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Dr. Griffith makes his position perfectly clear, and to me quite satisfactory, with the exception of his use of the word "hæmatoma," to which I have many objections. Amongst these I might mention that it is used for an altogether different kind of disease in various parts of the body. In the second place it is unnecessary, as "hæmatocele" answers every purpose, and with greater precision. In the third place it is given on the authority of Dr. Matthews Duncan, in whose writings confusion reigns supreme on the question of hæmatocele, as also on the somewhat analogous difficulty of "parametritis" and "perimetritis." Finally, the employment of a new term in medicine always suggests the idea that some new discovery has been made, while as a rule nothing of the kind has been accomplished. It would be, therefore, in every way better if the word "hæmatoma" were not introduced here.

I am, &c.,
Birmingham, Feb. 24th, 1887.
Lawson Tait.

HOMŒOPATHY AT THE MARGARET-STREET INFIRMARY FOR CONSUMPTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Your readers will no doubt be anxious to know the further history of the struggle of the partisans of scientific medicine to rid this Institution of the contamination of homœopathy. The adjourned Special General Meeting was fixed to take place on February 16th. In order to secure a large attendance of governors favourable to the cause of orthodox medicine, a circular signed by fifteen of the governors, including six of the medical staff, was circulated among the subscribers, earnestly requesting their attendance, and stating that the majority of the medical staff had declared their intention to resign if the homœopathic practices were continued in the infirmary. The meeting was accordingly held under the presidency of Lord Grimthorpe. The attack was commenced by one of the clerical members of the Executive Committee, who made a rather feeble speech and proposed a motion to this effect: "It having been proved that Drs. Jagielski and Marsh have treated patients in the Infirmary homœopathically, that Dr. Jagielski's name appears in the Homœopathic Directory, and that Dr. Marsh is on the Staff of the London Homœopathic Hospital, these gentlemen be requested to resign their position on the Staff of the Infirmary." This motion was seconded by a lay member of the Executive Committee. The same governor who had carried his motion against the seven members of the medical staff, and the Executive Committee at the Annual Meeting on the 26th January, and who, I find, is a well-known practitioner of the homœopathic school, rose and proposed an amendment to this effect: "That any attempt to limit the liberality of opinion or practice of the medical officers, is not sanctioned by the laws of the Infirmary, is prejudicial to the interests of the Infirmary and its patients, and is opposed to the spirit of the Medical Act of 1859." He made a long speech, filled with the usual clap-trap about the inherent right of every medical man to adopt any remedies or any method of treatment he thought best for the cure of his patients, about the inconsistency of members of a liberal and scientific profession not allowing for their colleagues that liberty of opinion which they claimed for themselves, and without which no scientific progress was possible, and he talked the ordinary stuff about persons who had not tested homœopathy, pretending to be better able to form a judgment about it than those who had, and so forth. The amendment was seconded by a lay governor. Dr. Cholmeley, one of the *consulting* physicians, argued that homœopathy was not recognised by the great body of the profession, and was not practised along side of the ordinary method in any of our hospitals, and, therefore, should not be allowed in the Infirmary, but he made the damaging confession that he had no particular prejudice against homœopathic treatment, for he sometimes prescribed homœopathic medicines himself; on which the Chairman said: "Then you do not object to the members of the medical staff doing likewise and prescribing homœopathic medicines?" I don't remember what Dr. Cholmeley replied to this, but I fear his confession made an unfavourable impression on the audience.

The only other person who spoke was another clerical member of the Executive Committee, but I thought his speech was very little to the point, and was delivered in the usual *de hæretico comburendo* style of the theologians, and as he of course had no knowledge of medicine, his opinion of homœopathy was of no value whatever. The two members of the staff who had introduced the hœomopathic innovation, spoke in defence of their action, and on the amendment being put to the vote, it was found that, 20 governors present were in favour of it, and only 17 against it. So the Chairman, after putting the original motion to the vote, with the reverse result, declared the amendment carried.

Thus the homœopaths have on both occasions scored a triumph. It will be observed that in spite of the circular threatening the resignation of the majority of the medical staff, which was signed by 15 governors, the total number of votes given against homœopathy was only 17, which shows that the governors were very lukewarm on the subject, and would not take the trouble to come and vote in favour of orthodox medicine. Four of the chief lay supporters of orthodox medicine on the Executive Committe have, I am told, sent in their resignations, and I suppos the six members of the medical staff who signed th circular will now resign; but that seems a very lame an impotent conclusion, and is very like the process know as cutting off your nose to vex your face. Is there an way out of the *impasse?* I confess I can see none. I was, I think, a great mistake having only one medic speaker on the orthodox side, and he, I must say, singularly ineffective one, and leaving the defence scientific medicine to a couple of clergymen who could n speak with any authority on a purely medical subjec Altogether we have made a sad bungle of the matter, an have only proved that, as the laws stand, the practice of the medical staff, even should they introduce the most heretical treatment, cannot be interfered with. The laws could of course be modified to meet the case, but what hope have we of being able to effect an alteration of the laws, which requires a majority of two-thirds of the governors, when, as this struggle has shown, we cannot command a simple majority on our side?

I am, &c.,

London, 28th February A Governor.

Medical News.

Army Medical Service.—The following is a list of candidates who were successful for appointments as surgeons in the Medical Staff of Her Majesty's Army at the competitive examination held in London on the 14th and following days of February, in order of merit:—

	Marks.		Marks.
H. E. H. Smith	3390	J. Paterson	2815
G. F. Alexander	3290	J. E. Trask	2800
W. P. Gore-Graham	3210	G. H. Forbes	2785
E. M. Woods	3195	E. C. Freeman	2755
C. S. Spong	3140	V. H. W. Davoren	2730
W. B. Leishman	3125	R. J. Copeland	2720
G. T. Rawnsley	3060	A. P. Blenkinsop	2670
J. Thomson	3040	A. L. Borrodaille	2640
C. W. Reilly	2990	W. Halloran	2640
W. J. Crofton	2895	T. Birt	2630
A. Wright	2880	H. S. Peeke	2630
A. J. Luther	2350	R. H. Smyth	2630
J. Girvin	2820		

Volunteer Medical Staff Corps.—On Friday last, Lady Crawford distributed the prizes to the successful competitors in the above corps, at St. James's Hall. Among those present were Sir Thomas Crawford, K.C.B., Sir V. Kennett Barrington, General Freemantle, Assistant Adj.-Gen., General Sussex Milford, Sir James Hanbury, K.C.B., Colonel Rutledge, Colonel Lumsden, Sir Herbert Perrott, Bart., Sir Edward Sieveking, Sir William MacCormac, Sir Dyce Duckworth, Sir Joseph Fayrer, Dr. Ord, Dr. Matthews Duncan, Mr. Morrant Baker, Mr. Furley, Mr. Croft, Surgeon-Major Hector, Commanding Officer at Aldershot, Surgeon-Major Faris, and a very large attendance of ladies and gentlemen. The prizes were numerous, and many of them of considerable value, some having been presented by friends interested in advancing the welfare of the corps. The following is a list:—Challenge Shield, awarded for the year to the best all-round company in drill, &c., won by No. 4 company; Messrs. Savory and Moore's prizes (value £5) awarded to the best stretcher detachment at ambulance waggon drill, won by St. Thomas's Hospital detachment, Sergeant Eccles, Corporal Fincham, Privates Dalzell, Isaacs, and Chambers; Messrs. Maw, Son & Thompson's prizes (value £5), awarded to the best detachment at stretcher drill, won by University College Hospital detachment, Sergeant Locke, Privates Cleveland, B. R. Clarke, and E. W. Hore; Messrs. Burroughs, Wellcome & Co.'s prize, a medicine chest, value £10 (or surgical instruments, at the option of winner), given for the best essay on the subject, "The Portability of Drugs," won by Private D. Walsh, London Hospital; Messrs. Salmon, Ody & Co.'s prize (value £4 4s.), a pair of field glasses, awarded to the smartest non-commissioned officer in the corps, won by Staff-Sergeant Bontor, St. Bartholomew's Hospital; Messrs. Down Bros.' prize (value £2 12s. 6d.), a case of surgical pocket instruments, awarded to the man neatest and quickest in applying bandages and splints, won by Sergeant Locke, University College Hospital; Prizes by Surgeon-Commandant Cantlie—(1) For essay on modern stretchers, won by Staff-Sergeant W. K. Waterson, No. 4 company, and Sergeant C. A. Locke, University College Hospital, equal; (2) For complete and exact rules for attending a patient suffering from various injuries, won by Staff-Sergeant W. K. Waterson, No. 4 company; (3) For application of the triangular bandage, 1st, Staff-Sergeant W. K. Waterson, No. 4 company, 2nd, Sergeant Goldney, Charing Cross Hospital; Adjutant's Prizes (4), given to the most efficient man of each company: No. 1 company, won by Private Rugg, King's College Hospital: No. 2 company, won by Private Dixon, London Hospital; No. 3 company, won by Corporal Skelding, St. Bartholomew's Hospital; No. 4 company, won by Corporal Franks, No. 4 company. Prize for the neatest kept tent at Aldershot Camp, 1886, won by St. Bartholomew's Detachment, Corporal J. G. Ogle, Lance-Corporal A. C. Lindsay, Privates H. Coates, H. W. Newton, W. B. Lane, and A. Pearce. Mrs. Cantlie's Prizes were won by Sergeant Goldney and Private C. Thompson. Besides the above battalion prizes, a large number of company prizes were taken by the following:—Privates Cleveland, H. C. Black, E. W. Hore, and B. Clarke, Lance-Corporal Wiggins, Privates Blucke, Thompson Winslow, H. Distin, and J. Penny, Lance-Corpls. Lees and Ridley, Corporal Bays, and Private Hatch, Corpl. Mould, Lance-Sergeant Bate, Corporal Watts, Private James, Corporal Ogle, Privates Oldham, Rawlinson, and Bennett (deceased), Privates Rawlinson and Chambers, Privates Dalzell, R. A. Dunn, and C. M. Welburn, Corporal Fincham, Private Heffernan, Sergeant Eccles, and Private Waller. After the distribution, speeches were made by Surgeon-Commandant Cantlie, Sir Thomas Crawford, &c., and the proceedings were concluded by a dinner in the large concert room of the St. James's Restaurant, when about sixty officers and friends of the movement were entertained by the corps, and, thanks to the zealous efforts of Senior Staff Surgeon-Commandant Cantlie, Surgeons-Major Norton, Platt, and Carson, and Surgeon Squire, a most enjoyable evening resulted. Sir Thomas Crawford ably occupied the chair, supported by the gentlemen before mentioned, and others principally belonging to the medical profession. In proposing the toast of the Public Medical Services, Dr. Ord delivered a philosophical speech on discipline, which he termed the subjection of the worser parts of man to the nobler ideal. Sir Joseph Fayrer, as representing in turn all the medical departments by actual service, responded, and Sir William MacCormac and Dr. Matthews Duncan replied on behalf of the Civil Medical Service. In proposing the toast of the Ambulance Corps, Sir James Hanbury passed a deserved eulogium on the work of Mr. John Furley, of the St. John's Ambulance Association, and after one or two more toasts, interspersed with music and songs, the company separated.

The Mortality of Foreign Cities.—The annual death-rates per 1,000 in the principal foreign cities, according to the last weekly returns communicated to the Registrar-General, are as follow:—Bombay 22, Madras 69, Paris 24, Brussels 22, Amsterdam 21, Rotterdam 22, The Hague 22, Copenhagen 23, Stockholm 21, Christiania 17, St. Petersburg 31, Berlin 22, Hamburg 28, Dresden 19, Breslau 31, Munich 21, Vienna 27, Buda-Pesth 34, Trieste 32, Rome 27, Turin 25, Venice 33, Cairo 39, Alexandria 33, New York 26, Brooklyn 20, Philadelphia 22, and Baltimore 17.

Vital Statistics.—The deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 21·1 per 1,000 of their population, and were—Birkenhead 24, Birmingham 23, Blackburn 22, Bolton 25, Bradford 20, Brighton 18, Bristol 20, Cardiff 23, Derby 17, Dublin 35, Edinburgh 23, Glasgow 27, Halifax 24, Huddersfield 25, Hull 18, Leeds 20, Leicester 17, Liverpool 25, London 19, Manchester 28, Newcastle-on-Tyne 24, Norwich 18, Nottingham 18, Oldham 22, Plymouth 25, Portsmouth 18, Preston 29, Salford 17, Sheffield 24, Sunderland 22, Wolverhampton 20. The highest annual death-rates in these towns last week were—From measles, 1·6 in Hull, 1·7 in Huddersfield, and 2·1 in Liverpool; from scarlet fever, 1·0 in Salford, 1·3 in Blackburn, and 1·6 in Bristol; from whooping-cough, 1·6 in Bristol, 2·0 in Sunderland, 2·3 in Huddersfield, and 3·4 in Plymouth; and from "fever," 1·0 in Preston. The 36 deaths from diphtheria included 15 in London, 3 in Glasgow, 3 in Portsmouth, 2 in Birkenhead, 2 in Liverpool, and 2 in Preston. Small-pox caused one death in Newcastle-upon-Tyne, but not one in any other part of the United Kingdom.

Notices to Correspondents, Short Letters, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attenion to this rule.

Reading Cases.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

THE TREATMENT OF PHTHISIS BY GASEOUS ENEMATA.

IN our issue for February 16th an article appeared from the pen of Dr. Alfred Drysdale, of Cannes, on Dr. Bergeon's method of treating phthisis. The article having attracted considerable attention, correspondents have written for further particulars, which the writer has kindly supplied at our request:—The carbonic acid gas absorbs the sulphuretted hydrogen and acts as a vehicle to convey it to the lungs; that it is entirely successful in this respect is proved by the fact that the patient's breath smells strongly of sulphuretted hydrogen a few minutes after taking the injection. The carbonic acid gas is prepared by the action of sulphuric acid on bicarbonate of sodium, and is kept rigorously free from atmospheric air, the injection of which into the intestines would cause great discomfort. It is then made to bubble through a sulphuretted water and on to the bowel. For the details of the operation we must refer our correspondents to the pamphlet alluded to by Dr. Drysdale at the end of his article.

DR. R. W. RAUDNITZ (Prague).—We cannot further add to our already extensive exchange list.

MR. GRESSWELL (Louth).—The proposal shall be considered, and a private note sent you.

MR. BLACKWOOD is thanked; the gentleman concerned has been communicated with.

ARTIFICIAL FECUNDATION.

WE have received several letters on this subject, but as it is one which it is undesirable to prolong in a public journal, we must refer our correspondents to the writings of the late Dr. Marion Sims, of New York. His practice is not one which met with approval when introduced some few years since in this country, and no useful purpose would be served by its repetition.

A GRADUATE.—We have already twice called attention to the condemnatory report of the Visitors of the General Medical Council upon the medical examinations of Dublin University. The Medical Council has the matter in hands, and the profession is pretty well aware that the report was most unfavourable. We, therefore do not consider it necessary to occupy space with a reprint of the article which you send.

"SKEGNESS HERALD."—The correspondent who sends us this paper and directs our attention to the fact that a person who calls himself "C. Colgrove Perry, M.D.," is emulating the lately expunged Dr. Robson in his newspaper laudation of Warner's Safe Cure, is informed that no person of that name appears in the Medical Register for 1886, and "Dr." Perry is, therefore, probably beyond the reach of remonstrance.

PLAYED OUT.—We are in some accord with you that the so-called Harveian and Hunterian orations are played out, and as you are a Scotchman, you must be aware of the old "saw" which implies that "ye canna tak the breeks o' a Heelanmon." Neither can ye now get or take any more out of Harvey or Hunter. Our great grandfathers knew as much or more about them than we do, and it seems nothing more nor less than an anachronism to be trying to resuscitate them in these cruel days. Swift, as you know, once wrote a pious meditation on a broomstick, and the G. O. M. could doubtless talk for twenty-four hours about the capacity of a cradle, or the points of a poker, but these are matter-of-fact days, in which every man has to fight as hard as he can for a living, and it is impossible for any man (however gifted he may be) to ring anything new or original out of this ten times "thrice-told tale." Harvey's Latin was simply barbarous. Hunter's style would shame a ditcher, and every one now knows how he ate and drank, stood or walked, snored or sneezed, so that the perpetuation of this annual commemoration has really become to be regarded with very qualified feelings.

MR A. WILSON.—Your notion of adding to our food resources in the direction named is to put it mildly, repulsive Doubtless you will be interested in Mottley's account of the siege of Paris under the Bearnaise in 1590. Look up your United *Netherlands*, if you have that book by you, vol. ii, p. 65, and see what he says:—"It was related, too, and believed that, in some instances mothers had salted the bodies of their dead children and fed upon them day by day till the hideous repast would no longer support their own life. . . . The Spanish Ambassador Mendoza advised recourse to an article of diet which had been used in some of the Oriental sieges. . . . . the bones of the dead were taken up in considerable quantities from the cemeteries, ground into flour, baked into bread, and consumed. All who ate of it died."

DR. P. A. R.—Attempts have been made to induce the profession to interest themselves in the question on several occasions; each has failed, we presumed on the principle that "what is everybody's business is nobody's."

MR. BOWREMAN JESSETT.—"Lectures on Tumours of the Neck, their Pathology and Treatment" received.

MR. REGINALD HARRISON (Liverpool).—"Notes on Some Cases of Urinary Calculus" received.

DR. E. MILNER.—Paper on "The Different Modes of Administering Mercury in Syphilis," received.

DR. A. D. (Cannes).—It is against our rule—unless under very exceptional circumstances—to insert letters that have been previously sent to contemporaries on subjects under discussion in those journals, and refused by them. Apart from this, in the present instance we were aware of the ridiculous anomaly, and pointed it out some two or three years ago when it transpired.

◆

Meetings of the Societies.

WEDNESDAY, MARCH 2ND.

OBSTETRICAL SOCIETY OF LONDON.—At 8 p.m., Specimens will be shown. Inaugural Address by the President (Dr. John Williams) Adjourned Discussion on Dr. Gibbons' paper on Unilateral Galactorrhœa.—Dr. Champneys: On the Separation of the Placenta.

THURSDAY, MARCH 3RD.

PATHOLOGICAL SOCIETY OF LONDON.—At 8.30 p.m., Mr. Godlee: Adeno-sarcoma of Tongue with Calcifying Nodule in Centre.—Mr. G. R. Turner: Alveolar Sarcoma growing from the Lumbar Spine. Dr. N. Moore: Malarial Diseases of Liver and Spleen. Mr. Lawson Tait: On the Pathology of Extra-uterine Pregnancy. Mr. Barwell: Cirsoid Aneurysm of the whole of Left Upper Extremity. Dr. Price: Cholesteatoma at Base of Brain. Mr. Fenwick: Metastatic Carcinoma of Prostate. Mr. A. Doran: Fibroma of the Ovarian Ligament. Card Specimens:—Mr. Gould: (1) Portion of Cervical Vertebræ expectorated from a case of Retro-pharyngeal Abscess; (2) Old Excision of Knee-joint. Mr. D'Arcy Power: A Rhinolith. Mr. Shattock: Colles' Fracture with Forward Displacement of Lower Fragment. Mr. A. Doran: Horny Growth from the Neck.

HARVEIAN SOCIETY OF LONDON.—At 8.30 p.m., Mr. Mitchell Banks (Liverpool): Extirpation of the Axillary Glands a Necessary Accompaniment of Removal of the Breast for Cancer. Dr. W. H. Day: Habitual Constipation in Children, and the Methods of Treatment.

FRIDAY, MARCH 4TH.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—At 8 p.m., Card Specimens:—Mr. H. Percy Dunn: (1) An Aneurysm of the Thoracic—extending into the Abdominal—Aorta; (2) Epithelioma of the Œsophagus. Dr. P. S. Abraham: Microscopical Sections of the Cervical Cord and Sympathetic Ganglia in a case of Exophthalmic Goitre. Living Specimens:—Dr. Scanes Spicer: A series of cases of Diseases of the Naso-pharynx. Papers:—Dr. J. B. Ball: Nocturnal Incontinence of Urine. Mr. R. Fitzroy Benham: Impacted Urethral Calculus, Perineal Section, Recovery.

ROYAL INSTITUTION OF GREAT BRITAIN.—At 9 p.m., Mr. Victor Horsley: Brain Surgery in the Stone Ages.

MONDAY, MARCH 7TH.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—At 8 p.m., Business: Casual Communications by Messrs. A. Winterbottom, F. Henri Weiss, A. S. Underwood, J. Ackery, C. Vincent Cotterell, and W. Harrison (Brighton). Paper by Dr. Dudley Buxton on the Physiological Action of Nitrous Oxide Gas.

Vacancies.

Ashton-under-Lyne.—House Surgeon for the District Infirmary. Salary £80 per annum, with board and residence. Applications with testimonials must be forwarded to the Hon. Secretary on or before March 8th.

Birmingham and Midland Eye Hospital.—House Surgeon. Salary £100 per annum, with apartments, board, and attendance. Applications with testimonials to be addressed to the Chairman of the Medical Committee on or before Thursday, March 10th.

Holborn Union —Medical Officer to the Workhouse at Mitcham, must reside near establishment. Salary £100, drugs found by guardians (see advert.)

Owens College, Manchester.—Senior Demonstrator in Physiology. Salary £150 per annum. Applications with testimonials should be addressed to the Senate not later than March 21st.

Paddington Workhouse Infirmary.—Assistant Medical Superintendent and Dispenser. Salary £100 per annum, with board, lodging and washing. Applications with testimonials must be sent in on or before March 5th to the Clerk to the Board.

University of Glasgow.—Examiners for Graduation in Medicine. The term of office will be four years. Applicants resident in Glasgow are not expected to give in testimonials, and those resident elsewhere, who may give in testimonials, are requested not to present more than four, which should be printed, and to be lodged on or before March 15th with the Secretary of the University Court.

Appointments

BOLTON, R. C. E., M.B, B.Ch.Dub, Medical Officer for the Sixth District of the Lincoln Union.

EMPSON, JOHN, L.K.Q.C.P.I., L.R.C.S.I., Medical Officer for the Milborne Port District of the Wincanton Union.

FOX, E. L., M.A., M.B, B.C.Cantab., M.R.C.S., Assistant House-Surgeon to the Liverpool Children's Infirmary.

LOCK, J. G., M.R.C.S., L.R.C.P.Ed., Medical Officer for the Third District of the Pembroke Union.

ROBERTSON, R., M.D.Ed., L.R.C.S., Visiting Medical Officer to the Netherfield Hospital for Infectious Diseases, Liverpool.

Marriages.

EUSTACE—SIBTHORPE.—Feb. 22nd, at St. Werburgh's Church, Dublin, Marcus Eustace, M.B., Alresford, Hants, eldest son of the late Marcus Eustace, F.K.Q.C.P.I., of Glasnevin, to Fanny, second daughter of Thomas Sibthorpe, Esq., J.P., Dublin.

HARLOCK—MARTIN.—Feb. 24th, at Defynock Church, Breconshire, Harry Harlock, L.R.C.P., M.R.C.S., of Singleton, Sussex, to Caroline, daughter of the late W. H. Martin, of Leytonstone.

WELSH—GRIFFITH.—Feb. 22nd, at St. Peter's Church, Brighton, Joseph Welsh, F.F.P.S., third son of the late William Henry Welsh, M.D., of Eccles, Manchester, and Clones, to Isabella Mary Jane Katharine, only daughter of the late Rev. William Williams Griffith, Rector of Heyope, Radnorshire.

Deaths.

HACKNEY.—On Feb. 19th, at Twickenham, John Hackney, M.R.C.S., L.S.A., aged 72.

LINDSAY.—On Feb. 21st, at Mickleover, Derby, J. Wallace Lindsay, eldest son of J. Murray Lindsay, M.D., aged 22.

MOCKLER.—On Feb. 17th, at Oxford Terrace, London, Edward Mockler, formerly Surgeon 17th Lancers, aged 77.

The Medical Press and Circular.

VOL. XCIV.] WEDNESDAY, MARCH 9, 1887. [No. 10.

Original Communications.

ON THE MANAGEMENT AND SELF-MANAGEMENT OF GOUT, OR THE URIC ACID DIATHESIS, AND THE "GOUTY."

By J. MORTIMER GRANVILLE, M.D.

(Continued from page 192.)

IN April, 1881, in a paper which appeared in the *Lancet* on "The Mental Element in the Etiology of Gout," I gave expression to the belief, formed long previously, that just as there is a "diabetic" centre, in the floor of the fourth ventricle, so there is a uric acid centre, probably located not far from the first-named. I was not aware, until after this announcement was made, that Dr. (now Sir) Dyce Duckworth had arrived at the same conclusion, and had expounded his views in 1880. I have therefore no claim to originality in the remark, and only now recall it in order to show that I have not either hastily or recently been led to attach a very high importance to the presence of an excess of uric acid in the blood in gout, the demonstration of which fact we owe to Professor Garrod, and to attribute the phenomena of the so-called disease "gout" to that excess as their proximate, though, of course, not ultimate, cause. The pathological, or perhaps I ought to say the physiological, difficulty seems to me to lie chiefly in the determination whether the error consists in an over-production of uric acid, or in its imperfect destruction or elimination, I say destruction *or* elimination, because if Dr. Pavy is right in his idea that the excess of sugar in diabetes is due to failure on the part of the liver as a "sugar-destroying," instead of a sugar-forming, organ, it may well be that the uric acid centre—assuming there to be one—inhibits the chemical processes by which uric acid should be either converted into something or quickly eliminated. Or perhaps there is something akin to excessive formation of uric acid, effected in a secondary and, as it were, incidental way, contingent upon error or defect in the assimilative or disassimilative processes generally. The facts, if not the inferences also, which Professor Latham brought before the Royal College of Physicians in the Croonian Lecture of 1886 furnish additional grounds for this conjecture.

The notion that an efficient cause of gout is to be sought, and can only be found, in the nervous system, dates from the time of Cullen, if, indeed, that strangely neglected authority in medicine was not himself its originator. He says:—"The gout is manifestly an affection of the nervous system, in which the primary powers of the whole system is lodged," but in propounding this hypothesis, Cullen repudiates the theory of "a certain morbific matter always present in the body, and that this matter by certain causes thrown upon the joints or other parts, produces the several phenomena of the disease;" so that clearly he did not entertain the possibility that a neurosis might produce morbific matter, and that, according to this view of the question, two modes of attack lay open to the physician, either to grapple with the deep lying cause of the malady in the nervous system directly, or to deal with its proximate cause, namely, the morbific—though not necessarily morbid—cause of the phenomena in the aggregate. The treatment I have been led to adopt, and which I have found, and am still finding, in a very high degree satisfactory, is conformable to this last-mentioned method, that is to say the elimination of the uric acid, and I am not prepared to concede that this is, even in theory, *palliative*—as distinguished from *curative*—treatment, because I hold it to be a cardinal principle of physiological medicine that functional errors can be best corrected by a re-educationary discipline, and the re-organisation of habits of health, as then even structural organic faults—in so far as they may be remedial by cultivation or development—may be mended through function. This application of the law of development by function and habit through the environment which Darwin has taught us, lies, I believe, at the root of a scientific and remedial art of healing, and I do not think the practitioner is well provided, at least as regards the very wide range of maladies which Sir William Gull has included in the phrase "field of pathology, without morbid anatomy," unless he perceives this fact, I have no right to imply that so high an authority as Sir William Gull would sanction my temerity in placing gout in the category of pathologies without morbid anatomy, but it is worthy of note that there is nothing essentially morbid, in the sense of being alien to the organism in the uric acid diathesis; and it is only by their secondary effects as mechanical obstructives or chemical irritants that the deposits of gout induce inflammatory action or provoke the outpouring of organisable extravasations. However this may be, I am fully persuaded that by dealing with the accumulation of uric acid in the blood or among the tissues, we can often accomplish much more than the mere temporary relief of the victim of gout, and that by persistence in the policy of elimination, we may not only obviate the consequence, but even remove the cause of that which for want of a more precise designation is termed uric acid disease or diathesis.

I think we may assume that it is mainly the metabolic function of the liver that is at fault in this disorder. Either the hepatic cells are themselves the subjects of some disabling organic peculiarity which has, perhaps, grown out of an inherited conformation, or these cells have fallen into a condition of impaired function from overwork and defective nutrition, or the nerves with which they are energised are exhausted or inhibited, or the supply of blood to the liver is excessive, by reason of failure in the action of the vaso-motor centre. It must never be forgotten that there can be no active dilatation of the arteries, and that dilatation is always due to failure of the vaso-motor centre, or the inhibition or antagonism of its energy. An excess of blood in the liver may occur, if the hepatic artery be dilated, producing disabling compression of the liver cells; or, if the portal vein be gorged with blood, over-charged with food from the stomach and intestines, this may produce an arrest of function from excess of delivery, as though the machinery of a manufactory were brought to a standstill by the too rapid inflow of raw material. In either, sometimes in more than one, of these ways liver-function may be impaired or arrested, with the result of a formation of uric acid in excess, probably in the manner elucidated by Professor Latham. In the face of this pathological position, however brought about, nothing can be more natural than that the physician should try to reduce chaos to order, by first cutting off, or greatly reducing, the supply of nitrogenous material. I freely admit that this seems the right thing to do, and yet strong as the argument in support of this view and the policy it suggests may be I do not myself adopt them. I believe it is better to concentrate attention on the outlet and then whatever, if anything, may be desirable in the way of limiting the ingress of nitrogenous material, may be postponed until the block is removed by opening up a free exit. My reason for this plan of treatment has been already suggested. I am convinced that it is impossible in any individual case to determine, off hand, how much or how little of the nitrogen consumed is essential to the maintenance of even such feeble vitality as may survive in the victim of acute, subacute, or chronic gout. I have seen patients with albuminous urine and heavily loaded blood, apparently groaning under the weight of accumulated waste, die quickly and directly after the withdrawal or reduction of an accustomed supply of food and stimulants, although presumably both were in excess. I make it a rule, therefore, never to cut off any food or drink until the blood has been unloaded by elimination, and it is shown by clear and conclusive evidence that the food and stimulants habitually taken are not necessary in the particular case under observation, after a free outlet of nitrogenous waste and excess has been established. Meanwhile direct chemical treatment is adopted with a view to rid the blood of its nitrogenous burden.

The principle of this treatment is the elimination of uric acid. I venture to differ, though with much respect, from the received authorities on the treatment of gout. I do not give alkalies to neutralise the acidity of the urine, nor do I offer the uric acid in the blood a base such as soda or potass with which to combine. It is, I think, preferable to break it away from the combinations into which it has already entered, and while providing a large quantity of fluid to wash it out of the blood, and through the kidney in solution, to avoid increasing, but on the contrary try rather to diminish the deposits of urate of sodium with which the attack of gout is associated. With this view I give iodine in the form of a tincture with glycerine; an infusion of serpentary, or pure water, being employed to dilute it. The clinical effects of this treatment are almost uniformly these: the strength is maintained, while the irritative fever is lessened, the pain is relieved, and the swelling is reduced. These happy results are, I believe, brought about by the simple process of rapidly ridding the blood of the uric acid, together with other products of imperfect metabolism. The urine becomes increasingly acid by reason chiefly of the elimination of oxalic acid with the uric, and it is either increased in quantity, or is more dense, without being increased, rapidly throwing down a shower of uric crystals. Under the most favourable conditions the total quantity of urine passed is simply immense, and its burden of uric acid is *proportionally* (*i.e.*, to the total quantity excreted) increased. This primary effect of its increasing the acidity of the urine lasts four or five hours only, and side by side with it there is an amelioration of the symptoms. I have in no instance, for some years past, in fact since I have treated gout by this directly chemical method had occasion to use colchicum or any sedative. The relief afforded has been immediate and effective. The only cases which have baffled my endeavour have been those in which morphia had been largely used previously to the attack or exhibited in it. I cannot tell why this effect should be produced by morphia, but it undoubtedly seems to antagonise the treatment and render it useless. The *rationale* of the use of iodine in gout is, I believe, as above stated, in the main a separation of the uric acid from its bases, but I am not sure that there is not also some destruction of the uric acid effected by its agency. As these are simply notes on treatment, I will not attempt the discussion of the chemical question this conjecture would raise. Suffice it to say that the practical results gained by the method in my experience, at least, surpass those attainable by other procedure, and, which is of considerable moment, the patient not only suffers less than usual during his attack, but his convalescence is shorter and the paroxysm is not so soon followed by another, when it is thus treated. Moreover, in the interval, he is not compelled to live the life of an invalid, and by the occasional use of the same remedies the deposits in and around his joints—which must, I think, be always regarded as unexploded shells left from previous wars—are progressively broken up and removed by the action of the iodine circulating in the blood. By a careful examination of the urine from time to time for quantity, specific gravity, acidity, urea, and uric acid, a fairly precise knowledge of the progress of the case may be obtained; and after watching a considerable number of cases for some years I cannot doubt that the method of treatment adopted is, on the whole, the most satisfactory. For the estimation of the acidity I use the phenol-phthaleïn test thus: pour 10 cc. of urine into a saucer, add a few drops of solution of phenol-phthaleïn (1 in 500 of spirit by weight), drop from a measured glass a *decinormal solution of soda* until a faintly red colour is permanent. Each cc. of the decimal solution of soda required to produce this ending equals 0·630 parts of acid per ounce, calculated as oxalic acid. Thus 5 cc. indicates 3·150 of acidity, and so on. For the urea I use the hypobromite test with the apparatus made by Hume, of Edinburgh, but I use the hypobromite of soda the moment it is made, before the heat evolved by the combination has been dissipated, and thus I find more than two per cent. of the urea. I find that above ten per cent. must be allowed for temperature, and pressure in reading the index. The whole process occupying only *three* minutes.

For, the uric acid I employ a modification of Professor Haycraft's test; thus take 5 cc. of the urine in a measured glass, add a few drops of a solution of carbonate of soda, and about a cc. of Liq. ammoniæ Fort. Shake these together, then add half a dozen drops of a solution of ammonio-nitrate of silver (made by dissolving 5 grammes of the nitrate in 100 cc. of water, and adding ammonia until the solution becomes clear). The urate of silver is now formed. This is a flocculent deposit which may be made to fall rapidly by pouring slowly on the urine thus treated some thirty or forty cc. of water which should be distilled. The deposit which falls will *approximately* represent about one-eighth of a grain of uric acid per ounce for each cc. of the space it occupies in the graduated glass at the end of ten minutes. There may be more accuracy in this computation, but it is easy for the practitioner to form his own estimate of the bulk of the deposit, at any particular time after the admixture, by making a few experiments with the full process as described by Professor Haycraft in the *Brit. Med. Jour.*, of Dec. 2nd, 1885, or my estimate may be accepted. It is not so much a question of the absolute accuracy of the quantitative analysis, as the relative proportions of successive analyses made with the same apparatus, and in the same way during the treatment of the case, so as to determine whether more or less of the uric acid is eliminated, regard being always had to the total quantity of the urine passed in twenty-four hours as this must obviously determine the value of the proportions of grain per ounce.

(To be continued.)

A COLONIAL and International Congress on Inebrity has been arranged to be held at the Westminister Town Hall in July next. The programme has been arranged by the Society for the Study of Inebriety, and a large number of men of eminence have promised to take part in the discussions.

Clinical Lecture

ON

THE TREATMENT OF TYPHOID FEVER. (a)

By Professor H. NOTHNAGEL,
Vienna.

(Continued from page 190.)

In this form of nourishment, water is in the front rank. You know now how important the administration of water is. You read in the journals of the foolish experiments which many people at the present time undertake who voluntarily submit themselves to treatment by hunger. You read that these people eat nothing, that they drink however, and we have known for a long time that people who from any cause fast, but at the same time drink, live considerably longer than those who both hunger and thirst; then the *exitus lethalis* takes place in a much shorter time. The indication to give patients water is so much the more urgent when they are insensible and they do not themselves request it. Those belonging to them, or the nurses must be instructed to give them water regularly; every quarter of an hour some milk or water or wine or the like must be given. The water must be good and pure, but it is best to give them boiled water. I must warn you of one thing, patients should not get "aerated" water to drink, especially when gurgling is present, as the meteorismus gets worse. Now as regards nourishment proper, we will not limit ourselves to giving our patients a particularly strong bouillon, upon which great stress used to be laid. Physiology has made it well known to you that bouillon contains very little that is food, it contains water and salts but albuminous substances only in small traces; it contains however a number of bye substances that act as aromatics and taste aromatically, the principal chemical substances and the potash salts, and you know that the smaller animals such as rabbits may be killed if bouillon be given to them in too great quantity by the influence that the potash exercises on the heart. The old view that bouillon is a food, and the more powerful the stronger, is thus not correct. We may give bouillon but we give it only as a vehicle for real foods. The foods that are given to such patients are the following:—I have introduced the rule into my klinik that typhoid patients get every day from a litre to a litre and a-half of good boiled milk, which they drink either cold or warm. When they turn against pure milk a little tea or a few spoonfuls of brandy are added, most of the patients take the milk readily. Besides the milk, such patients must get eggs, four to six yolks of eggs daily, this corresponds in nutritive value to about three eggs, if you give them soup in addition let the whites of the eggs be stirred up in it, but it must be quite smooth and not curdled. The patients thus take at least two, generally three to four eggs daily, I have given typhoid patients five to six eggs a day in a fluid form. Patients as a rule do not take raw eggs. You give them yolk of egg stirred up with sugar or salt, or it is better still if you have the yolk of egg mixed up with bouillon, chicken broth, pigeon broth, beef tea, and veal broth, farinaceous gruels, oat meal, rice, barley, &c., which may be employed as agreeable vehicles. Patients get on very well with this feeding. I now draw your attention to the following which is of great importance:—You place the maintenance of a human life in the hands of the nurses, in the hands of those who are about the patient. If they belong to the patient and love him everything is performed with the greatest attention, if they are strangers this is less so, and you must have a certain control. In the case of near relations a certain control is required, but from another cause however. When a person gives food to such a patient, he takes a few spoonfuls and will take no more, when he comes back in half an hour, the patient gets angry, he will take nothing and the by-standers do not insist upon it. The patient takes only half a glass, instead of the yokes of two eggs that he should have got, he gets perhaps only one, but yon are told that he has taken the broth. You must, therefore, have a certain control; it seems perhaps only a show, but I lay great stress upon it that there shall be a sheet near the patient's bed, upon which you may read at your visit:—11 a.m, patient took broth with yolks of two eggs, 11.30 wine, 12 milk, 1 milk, 2 broth with egg, &c. You give the food at intervals of from half an hour to two hours, and it must be plainly shown what the patient has taken. I cannot recommend this strongly enough, for the control of those in charge of the patient and of the nourishment he has taken.

This nourishment, absolutely fluid, water, milk, broth with yolk of egg, soup with white of egg, is continued until the patient is free from fever, and when they are not too far reduced, I generally wait for two or three days after the subsidence of the fever and then commence giving more solid food. The first food you can give is calves' brains or sweet-bread, then you may give cocoa and chocolate with egg, then cakes (English cakes or biscuit) which must, however, be quite soft, then, about six days after the subsidence of the fever, you commence to give them meat. In the case of patients brought very low, however, I would begin with meat before the fever is quite gone. The meat must be carefully prepared, it is best to give scraped smoked ham. You will do well however not to give the hams for sale here, they are much too fat, but what are called Westphalian hams, which can be watered a little if they taste too strong. Then we give scraped raw meat, from the loin, from a great piece of meat scraped off with a blunt spoon; if the pure raw state of the meat is disagreeable to the patient, a little salt is added and it is allowed to stand a couple of minutes in boiling water, in this way the raw taste disappears. The meat may be given in quantities of a coffee spoonful. You then gradually go on to other meats, the fillet is the best, roast beef, roasted in English fashion, and then gradually on to rolls and afterwards to a more solid diet. It is occasionally observed that patients who have quite lost their fever after the first meal of meat, get a slight rise of temperature again. These are things that you must know and you may prepare the relatives for it, but the rise disappears again after a day or two. A very important point is the administration of alcohol. Patients received, along with their milk, eggs, and soup, alcohol also. You know that formerly alcohol was condemned as a poison for such patients. Alcohol is given in the course of typhoid as a cardiac stimulant. But it is given for still more reasons. Formerly one was afraid to give alcohol, because it was the belief that alcohol raised the temperature. Then in the sixties the method of treatment became known to us, that was practiced in England, that of treating typhoid cases with spirits, liqueur, brandy, &c. This was followed up, and it was shown not only that no harm was done but that on the contrary the administration of alcohol was remarkably useful. After the fact became known, the attempt was made to ascertain wherein the usefulness of alcohol lay. A view was first made known the direct opposite of that previously prevalent, it was found that alcohol not only did not raise the temperature but actually reduced it, and there appeared about the close of the sixties and beginning of the seventies, a large series of labours from the laboratory of Binz and others, on the antipyretic action of alcohol. All these works confirmed the fact that alcohol reduced the temperature. For the first moment this sounds rather "baroch." When we take wine, beer, liqueur, in rather large quantity we experience congestion about the head, the skin becomes hot, and this has given rise to the view that alcohol raises the temperature. This is not correct however. Alcohol accelerates the circulation, it increases the activity of the heart, it causes turgor of the skin, cerebral hyperæmia, &c., and along with the freer access of blood a subjective feeling of heat; but the temperature within the body is lowered by alcohol. The hypothesis was thus set up that alcohol was useful as an antipyretic. But the temperature reducing action of alcohol is small, it is a matter of tenths of a degree (centigrade), and in the quantities in which we give it in febrile conditions the temperature is not reduced. We get greater reduction of temperature in the highest grades of alcoholic intoxication: when a man lies senselessly drunk his temperature falls. Wherein then lies the action of alcohol? The correct answer to the question has been given by Binz. Alcohol acts, to put it briefly, in the acute fibrile affections as a sparing agent (spar mittel) and thus indirectly as a food. By this the following is meant.

(a) A Clinical Lecture delivered in the Medical Klinik of the University of Vienna, January, 1887.

(*To be concluded in our next.*)

◆

SOME RARE PROFESSIONAL EXPERIENCES.

By Brigade-Surgeon W. CURRAN,
Army Medical Department (Retired.)

(*Continued from page* 117.)

Case VI.—Encephaloid Cancer of the Parotid.

Private John Sheehy, æt. 33, a large-sized muscular man, of temperate habits, was admitted to hospital at Nowshera on the 11th December, 1869, with a tumour of the neck on the right side, which appears to be attached to the jaw, and which was, he says, first noticed as a "kernel" in the parotid space, towards the end of August last. It was then detached and separable; it is no longer so now, and its nodular feel, rapid increase, superficial vascularity, and soft pultaceous consistence would appear to point to or imply the presence of malignancy. He complained towards the end of that month of a pain in it that resembled the prodding of a needle, while the skin that covered this swelling became tense and brawny, and it was in parts very sensitive to pressure. It subsequently assumed a dusky reddish hue, and looked here and there as if it would suppurate.

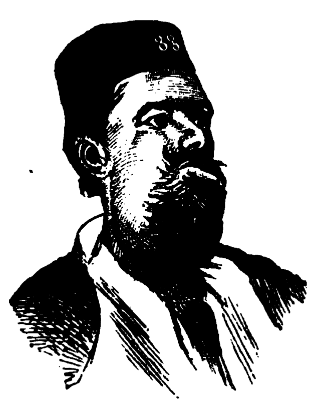
Though I had no longer any doubt in my mind as to its character, I yet thought it only due to him and myself to give him the benefit of such aid or advice as might be offered by others, and asked accordingly with this view for a consultation with my colleagues. This was held *secundum regulam*, and it was settled between us, *more medicorum consultatorum*, as well as, indeed, after a careful consideration of all the *pros* and *cons* of the case, that the rapid increase of this growth, the extent of surface involved in it, the vascularity of the surrounding tissues, and above all the state of the local glandular and osseous structures, precluded all hope of a satisfactory issue from active interference. It was, indeed, our unanimous belief that an operation which would probably necessitate the deligation of the carotid and the removal of a large portion of the lower jaw would only aggravate his present suffering, without offering any corresponding relief by way of return, and we were unwilling to precipitate a result that was in any case inevitable.

We also knew that no effort of ours could obviate or even delay this, and I am among those who think that the knife is too readily or too promiscuously resorted to in our day in these cancerous cases. A woman of my acquaintance who had a small and somewhat painful tumour in one of her breasts, was advised, nay urged, some twenty-seven years ago or more, by two London hospital surgeons, to consent to its removal at their hands. She declined, as is now, barring the accident of age, "as well as can be expected under the circumstances." Had this operation been performed at this time, she would probably not be here now to tell this tale, and the meaning of this recital lies, as Captain Bunsby would say, "in the application on it." I think that they would do just as well or better without it, and as to those hideous procedures, those worse than Bulgarian atrocities that are yclept "gastrostomy with tracheotomy," "pylorectomy," and above all—"Oh! name it not in Mercy's ear"—"gastero-enterostomy," I advise you, brother mine, to set your face like flint against such cruel but bootless butcheries—such unspeakable abominations. They can, as you know, do no good, while they must necessarily entail much individual inconvenience, if not, indeed, sleepless misery. At best they can only cheat death for a few hours, or, it may be, even for a few days of his prey. But what of that? and where is the use of such a painful prolongation of such a hopeless struggle. Better "end" it, I think, at once, than try to "mend" it, after the fashion here contemplated; and though we are told that

> The weariest and most loathed worldly life
> That age, ache, penury, and imprisonment
> Can lay on nature is a paradise
> To what we fear of death;

yet is there a medium in all things—especially so for the philanthropist or the surgeon—and were I myself in this predicament, I would, I believe, rather imitate the Roman of old, and "smite home" to the core than linger out for a few miserable hours or days, a spectacle to gods and men, or *worse*, the deluded victim of "a doubtful hope." (This, too, accords, I believe, with the practice for the later part of his life of that most able or accurate surgeon of our time, the late Prof. Syme. Anyhow, so I was, I think, told by a gentleman who had been at one time his house-surgeon; and so high was my opinion of that distinguished man's diagnostic acumen and skill that ever since he described the écraseur as "that preposterous engine," I have so characterised or considered it. I should much like to learn his opinion of that brutal abomination gastero-enterostomy. The very name is an outrage on etymology, and will never, I hope, be included in our nomenclatural terminology. Faugh! the foul thing savours more of the "stall" than of the surgery, and should like some other astomies or ectomies of its kind. "Not be so much as named amongst us.")

But *revenons à nos moutons*, and, discarding for the nonce those details as to treatment, &c., that must be familiar to all, I will here content myself with enumerating the more salient features of this case, and leave its minor points to inference and conjecture. Subjoining an illustration which is based on a photograph of the day, and which will give a better idea of the size, &c., of this swelling than any I could now indite. I proceed to say that all the above symptoms rapidly increased in severity. His breath became very offensive, his teeth were looser than before, his gums became boggy and œdematous, and we all remarked that his temper, "which was never of the sweetest," became more morose and irritable than ever.



He also began to lose hope himself about this time, and no wonder, for though a slight attack of localised erysipelas had somewhat relieved the pain or reduced the size of this growth, his worst symptoms soon returned, and we had, in a word, to transfer him, on the march, to the hospital of H.M.'s 6th Foot at Rawul Pindee. He died there somewhat suddenly of exhaustion (and possibly also of blood-poisoning) on the 25th of the following month, and the following meagre summary of his post-mortem appearances was subsequently furnished by the surgeon of that corps.

"*Post-mortem appearances five hours after death.*—The tumour was a soft cancer (encephaloid), apparently taking origin near the angle of the jaw, in the parotid gland of the right side. A small part of the bone of the lower jaw near its angle was bare, the periosteum being thickened if it was not ossified in this neighbourhood;" and so overwhelming was the stench that the examination was not carried farther. The gentleman who made it had the kindness to inform me afterwards that "the jaw was very little implicated, being merely stripped of its periosteum to the extent of a florin or so." He thought that it—the tumour—may have originated in the parotid gland, and if so, it would, I opine, be a specimen of that rare condition known as medullary cancer of the parotid.

Whether this was so or not, need not now trouble us, and one of my objects in reproducing it here is to say, as above, that I dislike the use of the knife, and in this and other rapidly increasing malignant growths of its kind. I believe, in short, that surgery is much less likely to prove of use in the removal of these lesions than in the treatment of almost any other of those diseases the military surgeon is concerned with, and whatever may be the result of this kind of interference at home—and he who runs may read my views of the situation—climate and the contingencies of service will always counsel abstinence in India.

I believe also that these cancerous diseases run a rapider course in the glowing East than they do in the colder West, and cancer of all kinds is, happily, rare in the army. So rare, indeed, is it, that this was about the sixth case of its kind, *at the outside*, that I saw in it in some twenty-seven years of service, and I am now quite satisfied that I, or rather we, practised with advantage rather than otherwise a policy of masterly inactivity in regard of it. The result would, I suppose, be the same in either case, with this difference, however, that there would be an aggravation of suffering in the first instance, and an exacerbation, or rather a precipitation of development and dissolution in the second, and *quieta non movere* is in this, as in so many other conditions of life, a safe and suggestive motto.

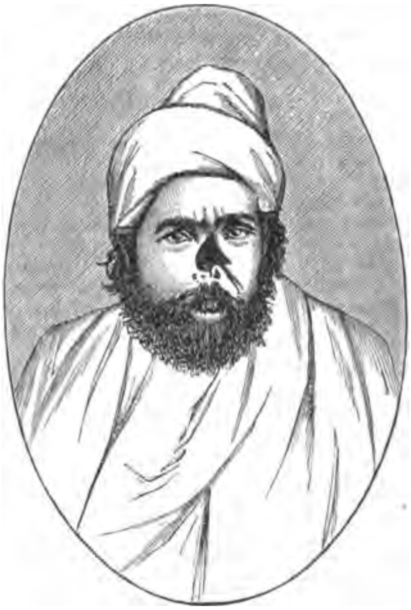
Case VII.—Peenash, alias Vermes Nasi.

Though some of the readers of this journal are familiar with the figure subjoined below, yet am I induced to reproduce it, partly because there is no such representation as it typifies in any book of my acquaintance in our own or any other language, and partly also because I wish to make these little "experiences" as useful and comprehensive as I can. Moreover, two distinguished members of the Indian Medical Service have written about it since I did, and they deserve a hearing at least at my hands. One of these, my old and esteemed friend the late Norman Chevers (a), after quoting from some of the instances that were referred to in my paper on "Eaten of Worms," thus delivers his testimony about it: "These valuable contributions to this subject will be found in the fifth volume of the *Indian Medical Gazette.* Dr. Alexander Gordon shows that in four years 303 cases of ozæna were treated at the Saharunpore Dispensary. Out of 168 cases which were sifted, peenash occurred in 63. Ozæna was found to be more frequent among females than among males, the persons being as a rule very poor, weak, emaciated, half-starved, anæmiated sufferers from fever, exposed to vicissitudes, and living a precarious life, the day's meagre meal most often depending on the day's wage.

No marked connection has been traced between this and malarial and other diseases of the liver and spleen, though such might be supposed to exist from the frequency with which epistaxis is met with as the first symptom. There was an undoubted syphilitic taint in some eight or ten of the above, and the disease occurs chiefly in the hot months of the year. It ends as a rule in recovery," as per our illustration below; and remembering the incidents of my own encounter with the subject of this lesion, I have often thought that the words of Horace,

Nihil habet infelix paupertas durius in se
Quamquod facit homines ridiculos,

would not be a bad description of the appearances it produces, or of the conditions under which it chiefly occurs.



The other "distinguished member" who is here indicated is Surgeon-General Moore (a), of the Bombay Army, and he describes it as "a malady almost entirely confined to the lower classes of dirty natives, and often the patient will be found to have suffered from some form of syphilitic nasal affection. In some instances, however, the primary condition may be scrofulous, or some other affection of the nasal mucous membrane. . . . The disease is caused by a fly—the blue-bottled—entering the nostrils and depositing larvæ, which eventually become maggots, and in the advanced stage the disease is one of the most disgusting and loathsome coming under observation. There is constant discharge of offensive pus, and occasional epistaxis, while the bridge of the nose gradually becomes depressed, then ulcerated and eaten away (as above), disclosing the interior of the nose filled with a seething coil of maggots."

"There is also much suffering from the movement of the maggots in the ethmoid cells, and these latter may also make their way through the palate into the mouth. These cases sometimes terminate rapidly, apparently from meningitis, but most frequently the patient dies worn out by suffering and debility. . . . . Maggots also appear in neglected wounds elsewhere (in India), and they generate in the same way in the nose of the camel. The piece of wood that passes through this beast's septum, and to which the driving string is

(a) "A Manual of the Diseases of India," p. 553.

attached, excites inflammation. Discharge ensues, and the ubiquitous fly is attracted." And for the rest, gentle reader, I respectfully invite you to turn for further particulars—if you require them—to what I have already said myself on these points in these pages.

Clinical Records.

A CASE OF SUPRA-PUBIC SUPPURATION.

Abortion (?) Constant Vomiting, Extreme Emaciation, Supra-pubic Abscess, Operation, Recovery.

By Charles Atkin, F.R.C.S., L.R.C.P. Lond.,
Lecturer on Anatomy, Sheffield School of Medicine.

Mrs. P., æt. 27, a ballet dancer, had had three children and one miscarriage. She had never been robust, but there was no family history of struma or cancer. She was taken ill in the beginning of July with violent griping pain in the lower part of the abdomen and pelvis. This continued for three nights, and then there was a discharge of blood (about half a pint) from the vagina. She had been under the impression that she was about three months gone in pregnancy. The discharge is stated to have occurred at intervals ever since. The medical man who was called in was at first under the impression that he had to do with a case of abortion, so ergot and opium were given. The pain, however, increased, vomiting set in, the tongue became dry and furred, pulse 120, temperature 100, pain and tenderness were noticed over the hypogastric region; the urine was scanty and was passed without much pain. When I first saw her, two months after the commencement of her illness, she was emaciated to the last degree, and was in great agony. As she was too sensitive to bear examination, ether was administered. The uterus was found to be not increased in size and fairly movable. The os was firm and would only admit the point of the uterine sound. A catheter was passed easily into the bladder. In front of the uterus and above the bladder was an ill-defined sense of hardness and dulness on percussion. There was no swelling in Douglas' pouch. An attempt was made to dilate the os, but it only partially succeeded. For some days she apparently improved, both the vomiting and pain ceasing, but, as the supra-pubic dulness became more marked, ether was again administered. A small median incision having been made above the pubes, an exploring needle was carefully pushed backwards and then downwards behind the pubes. Pus being found, a free incision was made and the cavity, which extended backwards to the uterus roofing in over the bladder, was carefully washed out and drained. The subsequent course of the case was, as I have been informed, an uninterrupted one towards recovery.

Remarks.—The cause of the suppuration is somewhat obscure. In the absence of a blow, great exertion may be deemed sufficient to bring on an abortion and subsequent metritis or cellulitis from depression of the vital energies. The pus, small in quantity (not more than 2 oz.), was very fœtid, and did not contain any broken-down blood-clot or cystic remains. The slow course and the lowness of the temperature were noteworthy. The vomiting at one time, probably before the actual formation of pus, was absolutely constant, everything, even iced water, being rejected. The pus was evidently tending forwards, but was some inches from the surface, why it did not gravitate downwards and discharge itself *per vaginam* is difficult to say. The exact anatomy of the fascia about the supra-pubic region seems to be a matter of doubt. The existence of a pre-vesical space, the so-called Cavus Retzii is stated by Roser, of Marburg, to be unjustified by either anatomical or pathological reasons (*Centralb. f. Chir.*, No. 39, 1886), and numerous cases are cited, showing that pus can push its way in any direction of the pelvis, and is not limited by any regular boundaries. On the other hand, Pinner, in the *Deutsch. Zeit. f. Chir. Bd.* 23, p. 463, describes two well-defined spaces—a submuscular and a pre-vesical one, injected with gypsum they each formed differently shaped swellings. The transversalis fascia is stated to split into two layers, one clothing the back of the transversalis muscle, and the other running down with the peritoneum on the summit of the bladder, and then leaving it to spread itself on the anterior surface of the viscus. Sir Henry Thompson makes no allusion to any such space in his monograph on the supra-pubic operation, but states that there is no danger of infiltration "unless there be unnecessary interference with the cellular connections, &c." In describing his method of operating, yellow fat covering the bladder is mentioned as coming into view as soon as the transversalis fascia has been divided, but no distinct second layer is alluded to. The value of anæsthesia and of the grooved needle are incalculable in these obscure pelvic affections. Exploratory punctures would often save cases such as the two following:—After an apparently successful herniotomy a low typhoid condition set in with obscure symptoms. On post-mortem a large pelvic abscess was found, which could easily have been tapped *per vaginam*. Another case of perityphlitis, discharging externally, died in a similar manner, and after death a collection of pus was found readily accessible from the vagina.

Transactions of Societies.

ACADEMY OF MEDICINE IN IRELAND.

Medical Section.

Meeting held Friday, January 28.

The President, Dr. James Little, in the Chair.

Dr. **Fitzpatrick**, as the senior member present, moved the following resolution:—"That the Fellows and Members of the Academy of Medicine in Ireland desire to place on record their sense of the loss the Medical Section has sustained by the death of Dr. Henry Kennedy, and to express their sympathy with Mrs. Kennedy and her children." Having known Dr. Kennedy for twenty-five years, he found him always desirous of fostering harmony and good feeling, while his great learning enabled him to promote discussion at the meetings of the Section.

Dr. **MacSwiney**, in seconding the resolution, said every member of the Academy would admit the great loss sustained by the profession in Dr. Kennedy's death, and the frequenters of the Medical Section in particular would miss his genial, kindly presence.

The **President**, in putting the resolution, which was unanimously adopted, said the members of the Academy would long miss Dr. Kennedy's familiar face and striking individuality of character.

TREATMENT BY "MASSAGE."

Dr. **Knight** exhibited a case under treatment by massage, manipulations being given by an experienced masseur.

Dr. **MacSwiney** asked (1) what was the ailment of the patient, and as to his being a typical case; (2) what the nature of the manipulative procedure; (3) whether the manipulator was a practised masseur; (4) what time was occupied in the process; (5) what result had been attained so far?

Dr. **Cox** said he had a case of neurasthenia in a girl, æt. 22, and he adopted massage, following, at the same time, the treatment as to diet, seclusion, and rest laid down by Mitchell. The result was satisfactory, following he believed much more from the rest and regimen than massage. He had himself submitted to massage by Jules Wulff, who sought tender points and manipulated these considerably, employing, as it were, centrifugal force moving from within outwards—first kneading or pinching the skin; next, the tissue beneath; and then the muscles, until the tenderness seemed to diminish; while he moved the joints freely in all directions. Massage was likely to be beneficial for local loss of power, the result of atrophy of the muscles or stiffness of joints in arthritis.

Dr. **Frazer** said Sir Astley Cooper, when he failed with a stiff joint, sent the case to a rubber, near Cambridge. For ages the Turks had been in the habit of using massage. The Japanese employed a similar process, filipating the surface of the skin till it became black and blue, with excellent results. This friction over tender parts was no novelty.

Dr. **Atthill** had experience of three cases which, having failed to be cured by medicine, were put under a course of massage, combined with careful supervision and enforced proper feeding; the good results, he thought, were more due to the treatment than to the massage.

Dr. J. W. P. **Kennedy** mentioned a case of intractable sciatica, for which the sciatic nerve was streched without the desired result. Three months afterwards the patient went to a woman in the County Meath reported to have great powers as regards massage; and under her treatment —rubbing from within outwards over the sciatic nerve—he recovered.

The **President** said affections of joints produed by rheumatism and the peculiar condition affecting the nervous system in girls were totally different things. He was himself, he believed, the first Irish doctor to place a patient under Wulff's care and the result was satisfactory. He would, however, never recommend a medical man to undertake the treatment of any of his own patients by the process, but transfer a case that baffled his medical skill to a new doctor and a new nurse.

Dr. **Knight**, in reply, said the case under treatment he believed to be suitable for massage, and the masseur had had many years' experience, having rubbed for Sir James Paget, Hutton and others. On Wednesday afternoon the patient was carried into the hospital, and he got his first rubbing at half-past two on Thursday, the time occupied being an hour, with the result that he got a good night's sleep, and walked down to the College this evening. There was arthritic trouble of the larger joints, but many of the smaller were affected. Massage was practised generally in the East, being called "hand-grasping."

CLASSIFICATION OF INSANITY.

Dr. **Conolly Norman** read a paper on variations of form in mental diseases in relation to the classification of insanity. The older classificatory schemes were briefly referred to. Objection was made to that of Dr. Skae, on the grounds that it gives undue prominence to all those causes of insanity which act indirectly and throws into the shade those acting directly upon the brain itself, and also that the term idiopathic insanity is too comprehensive to have any value. The ideal classification suggested by Dr. Savage is open to a similar objection—the insanity of maturity being a mere arbitrary phrase without physiological or pathological significance. The classification which the speaker adopted as most closely corresponding to the general facts of his experience is that of Professor von Krafft-Ebing, of Graz. The distinction which that author, in common with several of his countrymen, makes between psycho-neuroses and conditions of psychical degeneration he believed to be a genuine one, and of the greatest value from a prognostic point of view. There are, however, a large number of cases which it is most difficult to locate correctly in any classificatory system. Three cases were described in detail, all presenting very marked symptoms, which, nevertheless, the speaker had not been able to assign definitely to any one class, owing to the rapid and complete alteration of type which they had undergone. The first was a young male, of good family history, in whom no distinct cause of illness was ascertainable. He suffered from an attack of pure mania (exalted emotional state, with much incoherence and general excitement), lasting three months. He then passed into a condition of the profoundest stupor (acute dementia), which continued for nearly three months, and was followed by gradual, complete, and apparently permanent recovery. The second was a young woman whose family history was very bad, and who had been exposed to domestic trouble and shock. She suffered from intense suicidal melancholia for about nineteen months, then became maniacal and remained so till her death, two years later. The third case was that of a young man of dissolute habits and bad family history, who became insane after a bout of drinking. When the immediate signs of alcoholism had passed off he remained for some time in an exalted state, resembling a patient in the incipient stage of acute mania. With apparent suddenness he became depressed, attempted suicide, and fell into a condition of the most profound melancholia (pure emotional depression without delusion). These cases illustrated the difficulty of framing a satisfactory classification. Taking them to be pure psycho-neuroses, the symptoms of states usually held to be the most diverse succeeded each other in a manner that defied classification. On the other hand, an intermingling of discordant symptoms and an alteration of various mental states was one of the signs of psychical degeneration. No other clinical features in these case, however, pointed to the same conclusion, and they fell under no described class among the degenerators. They were not examples of *folie circulaire* (*folie à double forme*), neither were they cases of hebephrenia or kalatonia, two forms described by Kahlbaum, which often present a good deal of variation in symptoms.

Dr. **Fitzpatrick** regarded Dr. Conolly Norman's cases as simply cases of mania diverging into different forms. This was obvious from the fact that there were frequent cases in which the patient would be one month in a state of deep melancholia, and in the next exuberant with joyousness; and there were also cases in which mania ran into dementia.

Dr. **John Eustace** said the great point was to know what precisely the mental disease was, as then they might get at the *origo mali*, as, once the disease was ascertained, the doctor would have an aid in deciding as to its curability. Some classified mental disease according to the patients' acts, others according to their words. But a patient's deeds were of far more importance than his words. He did not agree that the stage of depression was the initial stage of cure. The natural termination of mania was dementia.

Dr. **Cox** complained that the study of insanity was left too much in the background, and hoped it would be made a compulsory study as in the Royal University.

Dr. **Frazer** concurred with Dr. Cox, and said no advance had been made in classification since Burton's "Anatomy of Melancholy," a work published two hundred years ago. Mental aberrations of transient character would be studied with profit, and were of more importance to the general practitioner than the graver forms which gravitated to the asylum.

Mr. **Wheeler** having also joined in the discussion,

The **President** hoped the observations of Drs. Cox and Frazer would bear fruit. The study of insanity was a want that existed, just as the necessity for a proper course in pathology. Dr. Conolly Norman had dealt with variations in the immediate symptoms of insanity as helping to a forecast of the result. Hence the value of classification; and he hoped the time was not far distant when the scalpel or object-glass would enable the surgeon to point out the traumatic changes lying at the root of insanity.

Dr. **Conolly Norman** replied, the great advantage of a natural system of classification was its prognostic value in predicating of a class a certain source, and especially whether curable or incurable. A large number of cases were due to hereditary influence, and, therefore, the existence of hereditary predisposition was a distinguishing sign for prognosis. Some classified mainly into general paralysis and ordinary insanity, but that system had not been accepted. He was pleased at the value attached to the clinical teaching of insanity.

◆

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Meeting held Feb. 17th, 1887.

The President, Dr. **Cleaver**, in the Chair.

CANCER OF THE LIVER.

Mr. **Coombe** showed for Mr. A. Jackson, a liver presenting a number of cancerous deposits in it. It was taken from a woman, æt. 52, married, the mother of two healthy children, both her parents living, and the family history excellent, who was admitted into hospital for schirrus cancer in the breast. Her own health, with the exception of two attacks of rheumatic fever, had always been good. The breast was removed on the 13th of January; followed by favourable action in the wound. She never recovered strength however, and sank steadily, dying on the 14th of February. At the post-mortem, the cancerous affection of the liver was discovered, apparently the masses were of the encephaloid character. Over each deposit there was a curious cup-like depression. Doubt having been expressed as to the patches in the liver being encephaloid rather than schirrus, the specimen was referred to the Pathological Committee for examination and report.

THORACIC ANEURISM.

Mr. **Coombe**, for Mr. A. Jackson, showed the morbid specimens in connection with this case, consisting of the sternum and about three inches in each side of the median line, closely attached to which was the ascending and transverse portion of the arch of the aorta which was enormously enlarged; to the aorta, the heart was attached and unopened. The sac was also unopened. The origin of the innominate, and left carotid, and subclavian arteries were involved in the dilatation. Over the upper portion of the sternum there was a large prominence which in life must have projected from two and a half to three inches, and measuring five inches from above downwards, and about four and a-half from side to side. The aneurism had burst in the second intercostal space, an inch to the right of the sternum. The specimen was taken from a man, æt. 46, a widower, with three children. He had always enjoyed good health, and by occupation he was a scissor forger. He was admitted into the Sheffield General Infirmary under Mr. Jackson's care, Jan. 8th, 1887, and died from the bursting of the tumour on the 31st of January. Twelve months previous to admission he noticed a small tumour about the size of a marble in the second right intercostal space. Enlargement of the tumour and thinning of its walls proceeded steadily to the end. Treatment seemed powerless to check it. Support by mechanical means seemed to be of the most service.

AORTIC DISEASE.

Dr. **Dyson** showed two specimens of aortic disease. One was taken from a man, æt. 47, a brewer's drayman. During life, a well-marked, high-pitched, musical murmur was heard (aortic diastolic), and a thrill felt all over the front of the chest. *Post mortem.*—The aorta was very extensively atheromatous and the valves much thickened, but no cause was discovered to account satisfactorily for the muscular quality of the murmur. The second specimen was taken from a woman, æt. 51, who had rheumatic fever. The valves were much deformed, one of them being split down the middle, the split segments being free to flap in the blood stream. The murmur in this case was a typical aortic diastolic one, but had no musical quality. Both cases had Bright's disease, and died of uræmia.

Mr. **Chas. Atkin**, F.R.C.S., read an interesting case of

SUPRA-PUBIC SUPPURATION,

which will be found under "Clinical Records," p. 218.

In the discussion which followed Mr. **Pye-Smith** mentioned the case of a man who came under his care for inguinal hernia, in support of which a properly fitting truss was applied, and after some weeks he returned, saying, he could not wear the truss. Upon examination, another lump was found inside his old standing hernia. Mr. Pye-Smith thought it was probably another hernia. As the second lump increased in size, the patient was admitted into hospital. Considerable doubt as to the real nature of the swelling. Further developments were waited for, but no signs of strangulated hernia appeared. Not consenting to have anything in the shape of operative measures done, he was discharged. Later on he returned, with a sinus in the upper portion of the opposite thigh to the side in which the hernia was, discharging pus pretty freely. The pus evidently crossed from the seat of tumour behind the pubis, to the point of discharge. In answer to a question by Mr. T. H. Morton as to whether the girl had sustained any special strain or blow, Mr. Atkin replied in the negative as far as the girl herself could give him any assurance on that point. Naturally there was a good deal of exertion and strain in the exercise of her professional duties.

LEAD POISONING BY DRINKING WATER.

Dr. **Porter** then opened a discussion on the above subject, and said that he felt a little diffidence in again bringing this subject before the Society, as it had been discussed already on more than one occasion; but, as some scepticism had been expressed in certain quarters as to the existence to any really serious extent of the evil referred to, and as fresh evidence of its existence had recently come under his notice, he felt that the importance of the subject, concerning as it did the health of the town, was a sufficient excuse for again intruding it upon their notice. He said that a year had elapsed since Dr. White, by his exhaustive report to the Health Committee, had first called attention to the prevalence of lead poisoning from this cause, and those who might be expected to appreciate the gravity of the danger had provided themselves with filters, warranted to exclude lead, and adopted the precautionary measures suggested; but among the lower classes, whose habits, occupations, and circumstances rendered them especially liable to suffer, the danger remained to a great extent unregarded. He then alluded to the slow and subtle nature of the poison, the peculiarities observed as to individual susceptibility, and the ill-defined and obscure character of the symptoms very often where the dose was very small, and the absorption of it extended over a long period. He admitted the difficulties of diagnosis in many cases, and the danger of too readily attributing to lead conditions which could not otherwise be accounted for; but he considered that to restrict the recognition of the disease to such well-marked indications only as "colic" and "wrist drop" was to overlook a large number of cases in which the health was being slowly undermined by smaller doses than were required to produce the more typical symptoms. He contended that at all events Dr. White, by his impartial report, had demonstrated the existence of a source of danger in our midst from the action of the Redmires water upon lead, whatever opinions might be entertained as to the prevalence of lead poisoning at the present time. Alluding to his own experience upon this point, Dr. Porter said that he had met with a number of cases since those he had referred to in his paper on this subject last year. Out of a total of 1,068 out-patients at the Sheffield Public Hospital under his care last year, he found 14 suffering from symptoms attributable to this cause, and 13 more who presented a more or less characteristic appearance of the gums, although suffering from other complaints, or considered doubtful cases. He had tabulated these cases, and now submitted them to the Society's notice. Of the whole 27 patients, 3 came from country districts outside the area of distribution of the Redmires water; but of the remaining 24, every one of them resided within this area. No less than 16 came from the Heeley, Highfields, and Washington Road neighbourhood, where Dr. White had shown that this action of the water upon the leaden service pipes occurred with the greatest intensity, and where in all the samples of water analysed a decidedly dangerous quantity of lead had been found. He passed round a diagram showing the situation of the districts of the town in which these cases had occurred, the patients' residences being marked in red ink. Seventeen of his patients were women, a fact attributable perhaps to their remaining more at home and consuming more of the contaminated water than the male members of the family. Eighteen cases came under observation in the summer or autumn months of the year, when no doubt more water would be consumed. Three patients had been, for a time, exposed to lead previously at their occupation, two having been file-cutters and one a type founder; but none of them had been so for some years. This fact, however, might render them more susceptible to the action of lead again. In conclusion, he said that he believed the danger from this action of the Redmires water had been under-rated rather than exaggerated, and would like to see steps taken for its prompt removal.

Dr. **Martin** thought that the fact of cases of lead-poisoning having occurred in Dronfield, the water supply to which is taken from a source presenting the same conditions as exist in connection with the Sheffield supply from Redmires Dam, deserving of being carefully considered since it seemed strongly to support the theory of lead-poisoning through water supply. Personally, he had not come in contact with many cases due to the water supply.

Mr. **Pye-Smith** had met with cases in the Broomhill and Sharrow districts. He mentioned one case specially, that of a woman who had a large lump in the abdomen which turned out to be fæcal accumulation. There was a decided blue line on the gums, great general muscular weakness, with frequent attacks of colicky pains.

Dr. **White** expressed his pleasure at the discussion being raised. He explained the intentions of the Sheffield Water Company with regard to filtration of the Redmires water, should they succeed in their effort to obtain a new Bill in Parliament. The filter beds are to be composed of a mixture of Derbyshire limestone and flint sand; the latter, it is asserted, prevents water acting upon lead.

Dr. **Keeling** had not met with many cases. He mentioned how he had sent specimens of the water from one of his patients to two chemists, eminent in their profession. From one he received the statement that there was lead in the specimen sent, from the other an assurance upon which he would stake his professional reputation, that there was not a trace to be found. Both of these men, he said, were strictly honourable, and worthy of all credence. He drew attention to what seemed to be a point of great interest and importance. Lead pipes of the present day are not as were the lead pipes of former times; they are incapable of standing the same strain from pressure. This is probably due to the improved methods which now exist for extracting silver from the lead ore. Owing to this condition of the pipes, when water is shut off suddenly, as it often is, from large works in the town, a sharp shock from the back flow is sent through the whole system of pipes, distension takes place, and fresh surfaces of lead denuded of the deposit which previously protected the inner surface of the pipe are exposed to the action of the water.

Dr. Dyson was not convinced that the water supply is to blame in all cases of blue line on the gums, where the occupation is not at fault. He has noticed blue lines as of very frequent occurrence in the case of domestic servants who wore false teeth. He had been told that lead enters into the composition of cheap mouth plates, and thought that these may prove a possible source of mischief. He had, however, seen at least twenty cases during the last twelve months of apparently true plumbism due to water supply.

Mr. Garrard, Mr. Richless, Mr. T. H. Morton, and Mr. Josiah Williams also joined in the discussion.

WEDNESDAY, MARCH 9, 1887.

FEES IN GENERAL PRACTICE.

One of the great wants of the profession in English general practice, is "a minimum scale of fees, to charge below which, would be considered unprofessional, and would entail upon the offender loss of caste, and deprivation of the privileges and courtesies of respectable practice." The want of such a scale tends very materially to lower the *status* of medical men in the eyes of the community at large. Those who give their services for say a shilling, or one shilling and sixpence a visit or consultation in the surgery, medicine included, reduce the value of such services to the level of the prescribing chemist or druggist, who makes the same, or even a higher charge, for the bottle of medicine he hands over the counter to those who are unwise enough to consult him. Something might be said for such low charges if they were rigidly confined to those whose circumstances rendered it impossible for them to pay on a higher scale. This excuse will not, however, hold good, as, in too many instances, the low charges are put forward merely as a bait in an unfair competition with the offender's medical brethren, whose charges conform to the scale laid down by the various ethical societies in different parts of the country as a guide to their members. *Auri sacri fames* is at the root of the matter. "Quantity, not quality," is the motto of such men. Cheap drugs and a large number of visits and consultations are the means relied upon. Some of these men boast of lists of eighty to a hundred visits a day, working horses and assistants night and day to keep abreast of the calls upon their time. Time for leisure, rest, and self-improvement is unknown; money, more money, is the one object in view, and any real love for their profession, or any real regard for the position its members ought to hold in the esteem of the public, is foreign to their nature. They are money grabbers pure and simple, not daring to trust to their work being valuable and valued by those who seek their aid, but entering into an ignoble and contemptible competition of cheapness to secure a *clientele*. The ordinary scale of general practitioner's charges are low enough in all conscience, when placed, the lowest in the scale, at two shillings and sixpence for a consultation in the surgery, medicine included; and, it is hard for a gentleman to accept such a sum in payment for what ought to be services of a much higher value; but the charge is supposed to be confined to those who cannot reasonably be expected to find more, and in this light alone is it accepted, and excusable; but, how any man, with any pretensions to being considered a gentleman, and with a gentleman's training, can charge, as a usual fee, a shilling, it is difficult to understand. We have heard it advanced that low charges should not form a bar to a man being considered a respectable practitioner, entitled to all proper consideration and courtesy at the hands of his medical brethren. If this proposition be true, there is no limit to be placed in the descending scale of fees. If a shilling be accepted as a legitimate and a sufficient charge, there is nothing to prevent ninepence or sixpence being the next steps in the downward scale. Such charges leave nothing to condemn in the so-called "provident dispensaries" with which the large towns in England are so plentifully besprinkled at present. At these places they charge sixpence a consultation at the dispensary, medicine, and such medicine!!!? included, and a shilling and one shilling and sixpence for visits at the patient's own homes, or in the case of the well-to-do, two shillings and sixpence. Most men of any standing in the profession refuse to have anything to say to the men who run these precious institutions, basing their objections upon the indiscriminate employment of unqualified assistants, to whom the qualified men act as covers, and further, of the impossibility of good drugs and brains being paid for by such low charges. We fear that, in all honesty, these objections apply with almost equal force to the proceedings of those who do not have the name of such provident institutions attached to their practice, but whose practice is, in reality, too nearly on the same lines, unqualified assistants, cheap drugs, and poor brains, being in too many instances quite on a par. We know that large incomes, nay, even tolerable fortunes, have been amassed by such means, but we cannot well envy such men, or hold them in the slightest respect. They may have succeeded in the object they had in view, but they are certainly not worthy members of a noble and honourable profession, which they have so prostituted to ignoble purposes.

To young men commencing practice the success and example of such men is a great and almost irresistible temptation to go and do likewise. Too often wanting in means and self-reliance, they make this practice of others an excuse to their consciences for doing the same, and so the profession of medicine continues to be dragged in the mud, and the services of its professors are held in light esteem. Ought such a condition of affairs be allowed to continue? Our answer would be unquestionably *no*. We may be asked what means we would take to remedy it, and what is the standard we desire to set up? Our answer must be, that, although professional charges must be reasonably low to the poorer classes, yet, there is no necessity to make them contemptibly so, and that the concensus of opinion gathered from what has been expressed in various ethical societies which have dealt with this subject, affords us safe guidance, as to what it would be right and proper to fix as the lowest scale of remuneration. This would be two shillings and sixpence, or in very exceptional circumstances, two shillings a visit, or consultation, for the poorest class of patients. Such a charge should be strictly limited to those whose circumstances demanded consideration, and should be looked upon, not so much as a matter of right, but of concession. It is a curious commentary upon the assertions of those who seek to defend low fees, that when the working classes lose confidence in the men who make them, they quickly resort to others whose charges are higher, and find means to pay them; and, further, do not hesitate to call in consultants, and find the money to pay them. Having fixed the minimum charge, any men making a lower charge should be regarded as placing themselves outside the brotherhood of the profession, and suffer the penalty of doing so. Consultants should refuse to meet them, and general practitioners should refuse to afford that help which may properly be looked for by those who conform to what is laid down as being within proper professional limits. In entering the profession, men should be prepared to face the conditions and responsibilities imposed upon them, and should be prepared to seek practice on legitimate grounds, and not by seeking to undersell their brother practitioners. No reform can be looked for so long as these low chargers and Cheap Jacks receive support from men who are engaged in legitimate practice. The only means at our disposal for enforcing the proper observance of legitimate practice is "the taboo." The carrying this into effect may seem a harsh measure, and one likely to bear hardly upon the public, until they are trained to the knowledge that, in accepting such cheap services, they cut themselves off from the benefits of help, and advice, from the better class practitioner. The taboo exists in the case of homœopaths; there is no valid reason, so far as the public are concerned, why it should not extend to men who are purely self seekers, and who do not hesitate to gain money in such a manner as to be altogether unfair to their medical brethren with whom they are in competition, and which must seriously derogate from the honour and dignity of the profession, of which they are most unworthy members.

Good quality and cheapness are rarely found in combination, and if a medical man's work is cheap it can rarely be good. If it is good, then the man who sets a low value upon his services is thoroughly selfish in the object he has in view, and is altogether unworthy of countenance and support at the hands of those with whom he has entered into what is manifestly a course of unfair, therefore unjustifiable, competition. If there are amongst the poorer classes people who cannot afford to pay the low scale of charges mentioned above, and yet who are not entitled to the medical attendance provided by the Poor-law Medical Service, it is to such the benefits of our great charitable institutions ought to be extended, and amongst whom well organised efforts to provide true provident dispensaries should be carried out, the advantages of which should be rigorously restricted to those only whose circumstances justified such consideration. Much more might easily be said about low fees and their effect upon the social standing of the mass of general practitioners in England; but what we have to say further must be allowed to stand over to some future occasion. In connection with this subject, however, we may safely assert that, with regard to it as to many other subjects connected with the well-being of the profession, the Medical Council has failed to do its duty, and has proved as useless as it has in most other matters which might prove of real benefit to the mass of general practitioners in the country if properly dealt with. The licensing bodies have also fallen lamentably short in their duty, in not insisting upon their licentiates observing strictly the lines of respectable and legitimate practice, under penalty of forfeiture of their qualification to practice.

Lastly, the great body of respectable practitioners whose fees bear some reasonable proportion to the value of their services, and, at the same time, show proper consideration for the circumstances of their patients, have fallen far short in the fulfilment of their duty in not coming to a general agreement as to what is, or what is not, a proper minimum fee to charge, and then rigorously enforcing its observance by treating as unprofessional men those who seek to gain practice by under-selling their neighbours. For the sake of the profession we hope this question may yet be taken up, and be placed upon a proper basis. As it is, there is a mean money grabbing spirit abroad, which leads some medical men to vie with their compeers, not in good work and placing a proper estimation upon their services, but, as to who can make the lowest charge, and so attract the greatest number of patients. At best it is a miserable and suicidal policy to pursue, and it ought, if possible, to be speedily stamped out by all right-minded members of the profession, aided of course by the licensing bodies, in all cases with those who offend in this matter. Unless some steps are taken, the steady depreciation that is going forward in professional self-respect will continue and make rapid headway, and do infinite damage to the professors and profession of medicine.

◆

ARMY MEDICAL GRIEVANCES.

We are obliged to confess to having failed to grasp or to understand clearly the points in respect of which army medical officers seek, by an amendment of the Service Warrants and Regulations, to obtain redress of what they consider to be grievances. We are, of course, conversant with several matters complained of which clearly involve injustice and hardship, and respecting which there can be no doubt or question, but beyond these we cannot get, and for a reason for which not we, but the army medical officers themselves, are to blame. We do not find amongst them a community of opinion an interchange of ideas, or an organisation such as can reasonably be expected to influence public feeling or exercise any serious pressure on the authorities, and our anxious inquiries from individuals seem only to lead to our bewilderment. For example, we are addressed by a young officer serving at home, who unfolds to us his woes and excites our sympathy. Before putting his case on paper we resort for corroboration to another informant, a Surgeon-Major home from Indian Service, who at once pooh-poohs the complaint, and substitutes one of his own, which he represents as far more deserving of consideration. Proceeding to check off these statements by a third informant, a Brigade Surgeon, associated more or less closely with the Army Medical Executive, we are assured that neither of these complaints have anything in them, that the complainants are very well off, and that their grievances are imaginary. We may explain that during the past quarter of a century the spirit of "reorganisation" invaded certain of what were then, and are still known as "civil" departments of the army. Among these departments, the medical obtained various important advantages beyond what had previously been extended to it; relative rank, as compared with actual rank of combatant grades, was accorded to medical officers on a scale more in accordance with the importance of the duties performed by them than existed at the time of the Crimean war; and since that time, until very recently, one improvement after another has taken place in the position of medical officers, rendering the branch of the service to which they belong as popular a career for the young surgeon as at one time it had been unpopular. To the non-military man, indeed, the expression "relative rank" has little, or probably no, significance; in army circles, however, from the soldier in his barrack-room to the general officer in command, the fact is well understood and recognised by all, that the position and consequent influence of an officer is determined solely and entirely by his "rank," whether that rank be actual, brevet, honorary, or relative; in fact, it is to them incomprehensible that an officer can have the status of an officer and yet have no rank. Among other changes recently introduced among certain "departments" was that of granting to their officers "honorary" instead of "relative" rank as previously assigned to them, and also conferring upon them military titles in accordance with that relative rank, so that virtually the medical department gradually found itself in these respects separated from those other "civil" branches to which allusion is made. But this was not to be all. It is but a few weeks ago that the announcement appeared in the *London Gazette* that "relative rank in the army is abolished." It is not too much to say the feeling among officers of the medical staff created by that announcement is one of consternation. It may be all very well to say that the position of these officers remains precisely as it was before the announcement in question appeared; no doubt their personal position does so; but in reality, their "relative" position with respect to other officers is absolutely undefined, if indeed any "position" whatever can be claimed by them. In acting with regard to our brethren in the army as the higher authorities have done they would appear to have taken a step the result of which may be the reverse of conducive to the best interests of the Service generally. It is possible that they may have acted rashly, and that their better judgment may lead them to retrace their steps when the subject is brought to their notice, as doubtless it will in due time be by some representative of the profession in Parliament. An opportunity for so doing will arise during the discussion of the Army Estimates. We would, however, like to know whether army medical officers, as a body, have any views on the subject? If they have, why do they leave it to a few zealous individuals to carry on the war? and why do they leave in doubt their knowledge of the Warrant, their appreciation of its effects, or their interest in the matter?

◆

HOMŒOPATHY AT THE MARGARET STREET INFIRMARY FOR CONSUMPTION.

The precept that brethren should dwell together in harmony is not observed to the extent one might wish in certain hospitals. Some, indeed, are the site of constantly recurring disputes which end in a certain number of resignations, the vacancies being filled by men who for the time, are willing to accept the conditions which their predecessors had found inadmissible. That old-established institution, the "Margaret Street Infirmary for Consumption," has quite recently been the scene of a pitched battle between the orthodox practitioners and the homœopaths. After enduring for a time the notoriously heterodox views and practices of some members of the staff, the loyal portion made a determined effort to compel them to resign. Partly from a want of tact, judgment, and dexterity, and partly from the fact that the lay governors were tolerably indifferent to these professional disputes, of which they can hardly be expected to appreciate the importance and the scope, the attack was successfully repulsed by the homœopaths, and the only resource left to the objectors was to resign, which they did. Several letters on the subject from "A Governor" have appeared in our columns, and give a comprehensive history of the struggle. "A Governor," however, adopts an erroneous line of argument in our opinion. The deeply-rooted antipathy of most practitioners to having anything to do with homœopaths arises from the reprobation with which all honourable men must view the act of sailing under false colours. It is the lack of a genuine scientific basis which vitiates their method and their affectation of adhering to a system which is uncorroborated by fact, reason, or theory, is a sufficient excuse for their ostracism by the great bulk of the profession. There is nowhere desire to impose any particular doctrine or mode of treatment; this is left to the conscience and skill of independent practitioners; what we deprecated is, in the language of the Royal College of Physicians, the "assumption or acceptance of designations implying the adoption of special modes of treatment." Homœopaths are not the only, though the most obvious, sinners in this respect.

The prospect is not a pleasant one. In the dispute which we have alluded to, the opinion of the governors of long standing was swamped by the aid of a number of specially appointed governors of three to six months' standing. In hospitals where the Membership or Fellowship of the College of Physicians is made a condition of appointment, any derogation from the code of medical ethics above laid down, would be punishable by withdrawal of the diploma, and hence the holder would cease to comply with the conditions of his office. In smaller institutions, however, where the requirements are less severe, no such means exist for punishing infractions of the college regulations. The profession, however, will keep a vigilant eye on the candidates for the posts so vacated, seeing that no one who rightly understands his duties towards the profession will rush in where angels fear to tread. If the institution in question is to become a mere *succursale* of the Homœopathic Hospital—a course which depends upon the decision of the governors —then, of course, one will know what its position and principles are. No ambiguity should be allowed to subsist on this head; as the French say, a door is either open or shut and a hospital is either governed by the ordinary rules or it is not.

"A Governor" asks, what is to be done? The question is one which we may safely leave to the future to decide. It is no affair of ours if certain people choose to throw in their lot with the homœopaths. They and the institution with which they are connected, will cease to enjoy the confidence and respect of the vast majority of their fellow practitioners, and if they are proof against this, the only course is to allow them to wallow in their heresies.

Medical men should think over their reasons for ignoring homœopaths, so as to be enabled, when necessary, to give a reason for the faith that is in them. They must convince the public that their attitude does not arise from any wish to restrict or limit the scope and field of practice, but simply and purely from a dislike for the use of designations which are misleading and contrary to the respect and dignity of the profession. We shall watch the further course of this affair closely and with interest.

◆

Notes on Current Topics.

Special Hospitals.

One needs but to glance at the ever-swelling list of special hospitals to be made aware of the additions which are constantly being made to their number. They increase in two ways, principally by segmentation, but also, contrary to generally received biological notions, sporadically, that is to say, they spring into existence by a mere effort of the will on the part of certain quasi-philanthropic gentlemen. A good example of the first method is the new "London Hospital for Diseases of the Throat and Ear," which has taken unto itself a form in Great Portland Street, and the staff whereof consists mainly of the gentlemen who found themselves unable conscientiously to retain office at the institution of which Dr. Morell Mackenzie is the guardian angel. The newer institutions naturally do their best by a carefully devised analogy of title to confuse the public as to "which is which," but success in this involves sailing rather near the law in so far as concerns the property of title. It is not impossible that an effort may be made to bring this fact home to the new hospital. It is remarkable that when Dr. Morell Mackenzie first opened his throat hospital, now nearly twenty-five years ago, our two contemporaries were strongly adverse to his doing so, and indulged in some very strong language in reference thereto. The lions must have had their claws pared, for quite recently the same journals announced the nomination of the staff of the new throat hospital without so much as a murmur. So long as these institutions are considered and treated as purely commercial ventures, we have nothing to say, but before being allowed to participate in any public funds they ought to be called upon to show in detail the use they make of their money, and to prove that the benefit they confer on the public is commensurate with their demands on the public purse. Mendicity, if authorised at all, should be under strict control. There is really no valid reason why the public should be exposed to importunate demands unless the necessity and the proper employment of the money subscribed has been clearly and officially demonstrated.

Professor Bandl, of Prague, has resigned his Professorship, and removed to Vienna. His successor in the professorial chair is Dr. Schauta, of Innsbruck.

Degrees for London Medical Students.

The agitation in support of the scheme which is now under consideration by the conjoint committee of the two London Colleges is being vigorously prosecuted. Numerous and enthusiastic meetings have been held at most of the medical schools of the metropolis in support of the plan, and the greatest unanimity of opinion prevails between teachers and students on a question of such vital importance to the future of Medicine in London. A step has been taken within the past week, however, which may very seriously affect the success of the movement for giving London students and practitioners the title of Doctor of Medicine. The Irish Colleges have taken alarm, and have agreed together—after conference—to put in their claim for the power to grant a similar title, if such power is given to the London Colleges. They do not appear specially desirous of the privilege of granting a degree which does not seem to justly belong to them, but they are determined to insist—before the Privy Council and Parliament—that all licensing privileges conferred on other colleges shall be extended to them. The claim seems a reasonable one ; we do not see how it can be resisted by Government or Parliament ; but it is not likely that the University of Dublin and the Royal University will stand by and see the Irish Colleges set up as grantors of University degrees, so that a complicated controversy on the subject may be expected.

Foreign Obituary.

The deaths are announced of—Dr. Leopold von Pebal Professor of Chemistry at Gratz; Dr. Beschütz of Salzwedel; Dr. T. R. von Huttern, Director of the Lainzer Lunatic Asylum in Vienna; Dr. Franc Günther, Emeritus Professor of Forensic Medicine at Prague ; Dr Bonnamy, Professor of Anatomy at Toulouse ; Professor Geigel, of Würzburg ; and Professor Ludwig Bandl, the eminent gynæcologist, of Prague.

The Therapeutics of Earthquakes.

The fortunate people who are enabled to seek health or shelter from an inclement season in the sunny regions of the Riviera have been seriously upset, in more ways than one, by the recent earthquakes. Many of them have thought it desirable to leave the unsettled districts in favour of more substantial if less favoured climes. Those who have experienced the curious and dreadful sensation of an unstable world will be inclined to regard with indulgence the ungovernable panic which seized upon the inhabitants of the disturbed districts with its *cortège* of lamentable and comical incidents. The effect from a pecuniary point upon the commerce of these parts cannot fail to be disastrous. In the present state of our ignorance concerning the therapeutical value of earthquakes few medical men will feel justified in exposing their patients to the risk of such violent physical and mental emotions as an earthquake—even if a small one—may procure. Doubtless there is a certain class of cases, hysterical paralysis and the like, which might distinctly benefit by the "earthquake treatment," but this method of treatment lacks precision in the present state of the science, and if ever this precision be attained, the object of the treatment will be surely frustrated, since the benefit, if any, will be dependent on the unexpectedness of the shock. A good deal of the damage done has been ascribed to the "jerry building" of the damaged houses, but it would be as well for English people to preserve a discreet silence on this point, seeing that a very moderate tremble in London would bring the greater part of our dwellings to the ground.

Lumbar Colotomy.

Mr. Croly performed left lumbar colotomy five weeks ago on a man, æt. 34, who was admitted into the City of Dublin Hospital suffering from malignant stricture of the rectum. The patient had been operated on in the Liverpool Royal Infirmary by internal division of the stricture, with temporary relief. His symptoms were very urgent when he came under Mr. Croly's care. The patient made a rapid recovery—was walking about the ward in three weeks, and has gained flesh. This is the ninth case of left lumbar colotomy operated on by Mr. Croly.

The Iodoform Craze

Is coming rapidly to an end, and those who have ridden the hobby so vigorously have descended, rather ashamed to have been seen at it. The imputation that iodoform in some cases produces toxic effects when used as a dressing for wounds has been followed by a denial that it possesses antiseptic properties. Messrs Heyn and Rovsing, of Copenhagen, report that in order to test its germicidal reputation they prepared solutions of iodoform in olive oil and serum, and studied their effects upon various bacterial organisms ; they also experimented on rabbits by mixing inoculation fluids with iodoform. Their experience was that in no case did the presence of the iodoform interfere with the development of micro-organisms, so that they conclude that as an antiseptic its employment in surgery is useless. Further, they point out that if this conclusion be correct, iodoform might itself act a carrier of pathogenic germs ; and they therefore recommend that before using iodoform, which is valuable as a dressing on other grounds than as an antiseptic, it should be disinfected in sublimate solution. *Quis custodiet ipsis custodes !*

Professor Zweifel, of Erlangen, has received a call to Leipsic, and Dr. Mikulicz, of Cracow, to Königsberg in Prussia.

Stonyhurst College is being visited by an epidemic, measles of a very virulent type. At the village of Hurst Green, less than half a mile from Stonyhurst College, nearly 50 per cent. of the children were found absent from school owing to the epidemic, and over thirty families were infected. The disease, which is said to have been brought from Germany, has caused four deaths in the College.

Earl Strafford, the Lord Lieutenant of Middlesex, will take the chair at the festival dinner in aid of the Royal Hospital for Diseases of the Chest, on Tuesday, May 10th, at the Hôtel Metropole.

The London Skin Hospital.

It appears to have become a rule almost without exception that out of each hospital dispute shall evolve another special hospital. Thus the original Hospital for Diseases of the Throat, in Golden Square,, is the focus from whence two or three others have sprung, one but a few days since, owing to the "Hospital Scandal" about which our readers are already aware; and now another skin hospital springs into existence, from a "scandal" at St. John's Hospital for Diseases of the Skin, Leicester Square, the centre of many previous eruptions. And on the principle that there is nothing like bringing sin home to one's very door, the "London Skin Hospital" has been opened in Cranbourne Street, within a few yards of its foster parent; and we are requested to announce that as an initiatory step of the Committee of Management, the following appointments have been made:—Mr. Jas. Startin, M.R C.S.; Mr. Walter Pocock, M.R.C.S.; and Mr. Edward Joseph Barry, M.D. Ed., M.R.C.S. Eng., to be Honorary Medical Officers to the Hospital; and Mr. Startin, Lecturer.

Poisonous Cheese.

Cases of poisoning from eating cheese are almost unknown on this side of the Atlantic, but according to Dr. Victor C. Vaughan, of the Michigan Board of Health, they are lamentably frequent. The symptoms are those ascribed to some varieties of ptomaines, viz. dryness of the throat, nausea, vomiting, diarrhœa nervous prostration, headache, and occasionally diplopia Though often severe, a fatal termination is rare. Freshly cut poisonous cheeses exude drops of an intensely acid fluid, and this fact should at once create suspicion. There would appear to be good grounds for believing that the poison may be generated by bacterial growth, but so far it has not been satisfactorily eliminated. The best results were obtained by making an aqueous extract of the cheese which is rendered alkaline by the addition of caustic potash; it is then treated with ether from which needle-shaped crystals are deposited. These crystals in solution gave rise to symptoms very like those caused by the ingestion of the cheese itself. Dr. Vaughan suggests that it may be one of the putrefactive ptomaines. He recommends, in consequence, more care in the inspection and cleansing of the milk cans, and greater attention to the cows, because if the surroundings are unhygienic and filthy, their milk is more liable to take on the putrefactive changes, to which the formation of the poison is supposed to be due.

Oil of Turpentine in Chronic Catarrh.

The attention of the profession is called to the value of oil of turpentine in chronic catarrhal inflammations of the pulmonary and respiratory tracts, by Dr. J. B. Walker in the American *Medical and Surgical Reporter*. In the form of tar the writer recommends the drug to be given in bronchial attacks, and he advises it under the form of terebene for such as cannot tolerate the crude preparation. His experiences confirm and extend the results gained in this country with pure terebene.

Compulsory Temperance.

Enthusiastic advocates of total abstinence from alcoholic drinks may well take a hint from the results which have been produced in Kansas, U.S.A., as a consequence of the prohibition of the liquor traffic. An enterprising local contemporary, published at Osage city, has been at the pains and expense of ascertaining to what extent drug stores are utilised there as sources of alcohol, and a somewhat startling though eminently instructive picture is presented by it. According to the laws regulating the sale of drugs in Kansas, intoxicating liquors may be purchased from chemists on the purpose for which its use, medicinally, is required being stated; and a list of three hundred and fifteen reasons for its requirement is given in this return, according to the New York *Medical Record*. Among the diseases named in this connection we find "bilious headache," "chronic diarrhœa," "chronic constipation," "congestion of lungs," "*indigestion*" of the same organs, a mysterious affection suggestively named "dry stomach," "gravel," "epilepsy,' "inflammation of the kidneys," and a whole host of others. The mere word of the candidate is all that is required in the way of diagnosis, nor need it be supported by any medical testimony to entitle to the purchase of spirit for relief of the symptoms. It must be clear, therefore, that though the drinking saloons may be effectually closed, there can scarcely be any limit to drinking habits among a population able to indulge habits of inebriety on such very flimsy pretexts as those named above. Moreover, if the more thorough-going of the agitators in this country had but their own way, and the regular drinking establishments were closed permanently, it is certain that something as bad, or even worse, would occur in this country. Intemperance can never be successfully fought by stringent measures of prohibition; but the constant inculcation of *temperance* will in time bear good fruit and lasting, and it is in this direction that the best results should be anticipated, as they will most certainly be obtained.

Thought-Reading and Instinct.

The question of thought-reading regarded in its scientific aspect is engaging a good deal of attention among physicians in America, where the phenomena attendant on it are being carefully investigated with a view to their explanation on physical grounds, in much the same manner as is being done in this country by the Society for promoting Psychical Research. An animated discussion in this connection recently took place at a meeting of the Massachusetts Medical Society, when a critical and instructive communication was read by Dr. Morton Prince, who, after sketching the progress of thought-reading and the experiments devised for illustrating its effects, arrives at the conclusion that the hypothesis which describes the phenomena as due to direct transference of thought from person to person engaged in experiment is not in itself inherently impossible, but that the subject must be considered as being still *sub judice*, and as requiring yet further investigation ere it can even be established beyond possibility of doubt. The conditions under which thought transference is possible are, in his opinion, very limited, and the ideas capable of such transference, themselves very simple, and he regards the number of failures recorded as tending to confirm the truth of the theory involved. Dr. Prince distinguishes clearly between the class of manifestations he deals with and those resulting from muscle-reading, and in this his critics in the following discussion on his paper in the main agree with him. One of these, Professor Royce, on the strength of a suggestion made to him by Mr. Barrett Wendell, of Cambridge, proposed to regard thought transference as dependent on the persistence of a trait existing in a former less cultivated condition of the human race, and an indication of a retrograde nature rather than a sign of advance. The nature of the phenomena he held to be indicative of a kind of "instinct," which may have been long obsolete in man, having been replaced by the higher attributes of human acquirement, particularly by speech, which has thus supplanted the ruder and more imperfect modes of communication formerly carried on by other and less comprehensive methods of conveying ideas. Such a conception of the *rationale* of thought-reading will possess a good deal of attraction for those who seek to harmonise facts with theories founded on a basis of evolution; and it has decidedly very much to recommend its consideration from this point of view. To what extent the suggestion may prove fruitful in the direction of future investigation remains, of course, to be seen, but that it will have some effect in this way can hardly be doubted, since not a few English observers have in a partial measure shown a leaning towards an explanation of the kind.

Unsuspected Nephritis in Children.

The occurrence of renal disease in young children is scarcely ever suspected or diagnosed except in those cases where it exists as a complication of some other affection, the urine of such patients not being made the object of examination as a matter of clinical routine. It is quite possible, therefore, that instances of diseased kidneys in such young subjects may continue unnoticed, even to a fatal termination, death being in the end ascribed to some totally different cause; and in this connection the experience of a single physician, quoted in the *Boston Medical and Surgical Journal*, has yielded no less than six cases within a few months, in which examination of the urine of infants under two years old had revealed undoubted signs of renal mischief. Within the same period, also, he had received reports of two other cases occurring in the practice of a friend, and in all of these, but for the fact of a special examination having been made, no indication of the true state of affairs would have been afforded. As to the method to be pursued with a view to procuring the fluid for observation, catheterism is the plan advised, though it is doubtful how far this means of collecting it will commend itself to general practitioners. That the warning sounded in the recommendation is a sound one, however, there can be but little question; nor can any great harm ensue from the more universal adoption of a suggestion which, especially in any case of unexplained illness among young children, may possibly be followed by the acquisition of useful and guiding information.

Advertising Dentists.

A person named Partridge, doing business in a sort of Dental Dispensary at Kensington, has applied to the law courts for a *mandamus* to compel the Medical Council to reinstate his name, which has been recently erased from the Dental Register. Mr. Partridge obtained admission to the examination for the Licence in Dentistry of the Irish College of Surgeons by signing an undertaking that he would observe the bylaws of the College, preserve its "reputation, honour, and dignity," and, specially, would refrain from advertising, and, if adjudged by the College to be guilty of violating this undertaking, would, at once, surrender his diploma to be cancelled. Having thus secured the title of L.D.S. which he desired, he at once proceeded to advertise, and otherwise violate the College by-laws, and, on his conduct becoming known, he was called upon to give explanations. He begged off, and apologised, and the College did not punish him as he deserved until they learned that he had again immediately proceeded to repeat the offence. They then called on him for an unqualified submission—apology—and renewed promise, and, as he equivocated and failed to conform to their demand, they struck him off their rolls, called on him to return his diploma, and notified his expulsion to the Medical Council, who, as a matter of course, struck out the L.D.S.R.C.S.I. appended to his name in the Dental Register, and *ipso facto* his name disappeared from the Register, and he became liable to prosecution for illicit practice. The newspaper reports of the case do not clearly disclose the law points upon which Mr. Partridge depends. It appears from the Dental Register that he was not registered as a dentist in practice before July, 1878, but solely as a holder of the L.D.S. Therefore he can hardly maintain that, notwithstanding the withdrawal of that licence, he is still entitled to appear on the Register. But perhaps he interprets the clause of the Dentists' Act as compelling the Medical Council to inquire, for themselves, the cause of his expulsion, and not to erase his name unless they are of opinion that he has been guilty of "infamous and disgraceful conduct in a professional respect." On this point the clause of the Act seems somewhat ambiguous, but it would be an absurdity to construe the law so as to compel the Medical Register to state falsely that this person is the holder of a licence which, in fact, he does not hold. If such an interpretation were possible, and that the Medical Council reinstated the record of the licence in connection with Mr. Partridge's name, they would then become liable to an action on the part of the College to compel them to abstain from degrading its licence by attaching it to a person considered by it to be disreputable. As to the expulsion of Mr. Partridge by the College, no question can arise, for it enjoys the most ample authority under its charters to expel a Licentiate for wilful breach of any by-law or regulation which it pleases to make. The issue of this suit is, however, of considerable importance, for if Mr. Partridge should succeed in his claim to be credited with the licence which the College has taken from him, then any Dental Licentiate may, with impunity, violate all his pledges and break the collegiate law without any apprehension of punishment, and it will become necessary for the College to insist on a money guarantee or else to refuse to grant the Licence in Dentistry at all.

Diabetic Dietetics.

Dr. Pavy has very properly called attention to the fact that a good deal of the so-called "gluten bread," &c., in reality differs but little from ordinary bread so far as the proportion of starch is concerned. The evil results of such fraudulent representations are obvious, and henceforth every medical man in charge of a diabetic patient should not be satisfied with ordering gluten bread, &c., but ought to assure himself that the article is really what it pretends to be. Much disappointment in treatment in the past may be attributable to this weak point, against which medical men have, perhaps, been scarcely enough on their guard. Gluten flour and gluten bread always contain a certain amount of starch, but this is not of importance provided the proportion do not exceed 25 to 30 per cent. Many of those examined by Dr. Pavy contained as much as 75 to 89 per cent. of starch. In bran biscuits, 50 to 60 per cent. of starch was found, but this included the cellulose and lignose contained in bran. Macaroni, vermicelli, and semola, also specially prepared for diabetic patients, were none of them really suitable, only differing to a slight extent from the ordinary article.

Treatment of Fissure of the Anus.

Dr. F. Mendel, of Essen, recommends in the *Deutsche Med. Zeit.*, No. 17, 1887, the following as a simple, comparatively painless, and effective method of treatment for this painful and sometimes obstinate affection. He commences by cauterising freely with arg. nit., and follows this at once by painting with a 5 per cent. solution of cocaine. This at once relieves the pain caused by the cauterisation. He then makes use of the following mixture as an ointment:—

Acid. borac., 2.0;
Cocain. mur., 1.0;
Lanolin, 20.0. M.
Ft. ung.

This is applied with the finger several times a day, and especially after defæcation, and retained by a pledget of lint. Care is taken that the bowels are gently acted on daily—Epsom salts, Carlsbad salts, &c., and the base of the fissure is cleansed several times a day by washing with a 3 per cent. solution of boracic acid. Within one or two weeks this method of treatment always induced healing of the ulcer, as the cocaine prevented the painful contraction of the sphincter ani, and the cleansing with the boracic acid prevented accumulation of irritating matter, fæcal or other.

Preventive Inoculation against Phthisis.

M. Vittorio Cavagius has reported to the Academie des Sciences, Nov. 29, that a two per cent. solution of carbolic acid destroys the infective power of tuberculous virus, that a weaker solution (1·25 per cent.) enfeebles or attenuates it. By inoculation of rabbits and guinea-pigs first with inert tuberculous matter, then with attenuated, he found that they were not made tuberculous, even when pure tuberculous matter was injected.

The Brussels M.D.

A list of the graduates of the University of Brussels residing in England and Wales has recently been published by the Brussels Medical Graduates' Association, from which it appears that their number now exceeds two hundred. Many of the gentlemen holding this degree occupy distinguished public positions in connection with various hospitals and institutions. This list is of interest in view of the application which will be made shortly to the General Medical Council to render the degree a registrable qualification in this country. Only men already qualified in medicine and surgery are exempted from the usual course of study and residence, and the numbers who have availed themselves of the opportunity show the necessity which exists for similar facilities in England.

Influence of Alcohol on the Interchange of Gases.

Dr. Bodlaender, of the Pharmacological Institute of Bonn, has been carefully revising the views held on the fate of alcohol in the system, and has published the results of his researches in the *Zeitschrift für Klinische Medizin*, 5 and 6, 1887. In opposition to the views of French and other authorities that alcohol completely passes out of the system, and unchanged, through the lungs, skin, and kidneys, Binz, of Bonn, and his followers, have shown that an insignificant fractional part only thus passes out unchanged—in the human subject about 2,915 per cent. The question whether this oxidation of the alcohol in the system, protects body material or food from combustion may be answered in two ways: 1. By a computation of the heat evolved; and 2. By calculating the amount of the products of combustion. (Water, urea, and carbon dioxide.) Dr. Bodlaender chose the second method, and arrived at the conclusion that, under the influence of alcohol a diminution of the amount of oxygen absorbed, and of the carbonic acid eliminated almost invariably takes place. Alcohol introduced into the system lessens combustion, it is itself consumed in the system, and thus protects the organism or other food introduced from oxidation; and so much the more as the total amount of combustion is not increased but diminished. This property renders alcohol an important article of diet in the sick-room; it acts not only as a stimulant and a febrifuge, but as food. As an article of food in health its nutritive value, economically considered, is, of course, out of all proportion less than that of the sugar and starch from which it is manufactured. It must also be borne in mind that if a sufficiency of these articles is taken, any alcohol consumed is then in excess of the requirements and likely to be rather injurious than useful.

The crematory furnaces which are being built in the cemetery of Père Lachaise at Paris have now advanced beyond the first story. The upper part and the chimneys, however, still remain to be added, and it is not expected that cremation can take place there before the end of the year. The completion of the original plan, which comprises waiting rooms for the public and temporary resting-places for the ashes, will only be proceeded with "s'il y a lieu" at a subsequent date.

Action for an Alleged False Certificate of Death.

On Saturday last a criminal prosecution was instituted against Mr. Thos. Wheeler, M.R.C.S., of Bexley, Kent, Medical Officer and Health Officer for the district, for that he wilfully did make and issue a certificate of death knowing it to be false. During the hearing of the case it transpired that Mr. Wheeler had been asked to see the deceased woman on December 19th, by her husband, a foundryman, and after giving directions as to what should be done for the patient, left, promising to call again. This he failed to do, although the husband sent or called on him three or four times, begging him to come again, as his wife was dying. The next time he visited her was on Dec. 25th, soon after she had expired, and a certificate was given that he had attended her on the 24th. On these grounds the action was taken; but the prosecution failed to gain a verdict, owing to the fact that the certificate of the cause of death was correct, albeit the date was wrong. After reading the shorthand evidence of the case, we reluctantly forbear to comment.

A dramatic performance, under distinguished patronage, in furtherance of the appeal for £100,000 fund for Guy's Hospital, will be given at the Novelty Theatre on Thursday, April 21st.

Dr. Brouardel, the well-known Professor of State Medicine, has been gazetted Dean of the Faculty of Medicine of Paris, *vice* Dr. Béclard, deceased. Dr. Brouardel is one of the youngest professors of the Faculty, being only forty-seven years of age. He will continue, notwithstanding his appointment, to deliver his lectures on legal medicine at the Morgue.

France.

[From our own Correspondent.]

Pasteur Again.—At a meeting of the Academie de Médecine, M. Peter again attacked the Pasteur method of treating rabies, and brought forward the testimony of two Italian doctors (Renzi and Amorso of Naples) which was to the effect that the malady could be produced by inoculation of the virus under the dura mater after trephining, but there were no prophylactic agents against the hydrophobia thus provoked. M. Vulpian, replied, observing that the experience of the two gentlemen was not very great as regards bacteriology.

Adenoma of the Breast.—At the Société de Chirurgie, M. Terrillon, spoke on a case of painful tumour of the breast. A woman, æt. 21, complained greatly of pain in the left breast, assuming a neuralgic form. The painful part was situated near the nipple, where some hard nodules could be felt. Medical treatment was tried without avail, and the patient insisting on an operation, the glands were taken out, when the pain immediately ceased. An histological examination revealed the presence of adenoma.

Bouchard on the Treatment of Typhoid.—M. Bouchard recommends the following treatment for typhoid fever, which comprises four principal points.—1st. A purgative every three days (half-an-ounce of Epsom salts). 2nd. Eight grains of calomel, daily (in half-grain doses every hour) for four days. 3rd. ℥iij charcoal in powder, xx grains of iodoform. ʒj of napthalin, the whole to be mixed with ℥viij glycerine and ʒj peptone. This mixture forms a treacley mass, and is administered in tablespoon doses every two hours in a little water. An enema should be also given morning and evening of a solution of phenic acid (1 in 1,000, the half each time). 4th. From the first day the patient takes eight baths daily, as long as the temperature exceeds 37 degrees centigrade (98 F.) The baths are only four degrees lower than the temperature of the patient, and thus no shock is produced, by degrees cold water is added until 86 degrees Farenheit is reached, that is to say, after an hour and half, and thus the half of the day is spent in the water. The *régime* comprises beef tea, lemonade and wine. This treatment gave a mortality of only 7 per cent. in the Lariboisière hospital, while hitherto, it exceeded 18 per cent.

Massage in the Treatment of Fractures.—M. Lucas Championnière cites a typical case by a medical man on whom the treatment produced the best results. In the month of August of last year, in getting out of the tramway, this gentleman twisted his foot, and experienced immediately great pain, and was obliged after limping a short distance, to take a cab to his home. M. Lucas was called in, and diagnosed a fracture of the fibula *par arrachement.* Immobility and daily massage avoiding the seat of the fracture were ordered. The pain and swelling diminished gradually, and twelve days after the accident he was able to put on a boot and walk. Another case not less striking, was that of the Surgeon-in-Chief of Prefecture, who fractured the radius in a fall from his horse. Massage was resorted to, and in 48 hours all pain had disappeared; in four days he wrote pretty fairly, and in two weeks he had recovered every movement of the arm. A substitute was only required to perform his functions two days during the whole time.

Reduction of Hernia.—At the Societé de Chirurgie, M. Terrier brought forward a case of internal strangulation caused by the reduction *en masse* of a hernial sac. The man was 61 years of age, suffered for a considerable time from an inguinal hernia of the right side which became frequently very troublesome to reduce. A few days ago the rupture presenting again symptoms of strangulation was reduced *en masse* and all went well for two or three days, but at the end of that time severe pain was felt over the seat of the hernia, the abdomen became painful and distended, and all the symptoms of stricture of the intestine soon appeared, the operation of laparotomy was performed and the suspicions of the surgeon were confirmed. The intestine was disengaged and the man made a good recovery.

Iodoform in Cold Abscesses.—M. Terrillon read a case of abscess of the gluteal region following typhoid fever and treated by iodoform dissolved in ether (1 in 20). The injections produced the best results, and he recommended the treatment to be employed in similar cases, that is to say, in cold abscesses, although he believed that the same method would be tried with benefit in inflammatory abscess. M. Terrier considered the communication of M. Terrillon worthy of attention, but nevertheless, was of opinion that cold abscesses even of tuberculous origin, could cure by a simple incision especially if pressure were applied. M. Le Dentu said that injections as proposed by M. Terrillon, of iodoform for cold abscesses were far from answering up to the expectations. He rather preferred incision of the collection of pus and cauterisation of the walls with a solution of chloride of zinc (1 in 20). He was of the same opinion as the last-named operator in regard to the spontaneous cure of the abscess. M. Reclus, however, was greatly in favour of the iodoform treatment so much preferred by M. Verneuil. He never saw any accident follow the employment of the solution, and on the contrary, insisted on its utility in fistulæ which are otherwise almost condemned to become permanently chronic. Your correspondent can fully verify the statement of M. Reclus. On a patient of his who was suffering from fistula of the axilla consequent on abscess in that region, cauterising with nitrate of silver, injections of irritating agents (liqueur violette), were tried in vain. In a fortnight after the adoption of M. Verneuil's method the fistula was completely cured.

Incision of the Vesico-Vaginal Wall for Purulent Cystitis.—M. Le Dentn cited two cases of incision of the vesico-vaginal wall for purulent cystitis accompanied with pain. First case was that of a woman, 41 years old, who had been admitted into the hospital for cystitis, accompanied with cystalgia of a very distressing character. A vesico-vaginal fistula was treated. At the end of three weeks the pain had entirely disappeared, and the urine became clear, six months subsequently the fistula was closed, and at present, the general condition was as good as could be desired. The second was a case of tuberculous cystitis, the same operation was performed with similar results as far as the urinary apparatus was concerned. The fistula in this case could not be closed on account of the pulmonary trouble.

Treatment of Syphilis by Subcutaneous Injections of Calomel.—M. Besnier, of the St. Louis hospital employs with the most satisfactory result, the treatment of syphilis inaugurated by an Italian physician named Scarenzio, and which consists in the subcutaneous injections of calomel suspended in vaseline oil. M. Besnier, in the treatment, takes every antiseptic precaution: the place where the needles are to be inserted is washed with a feeble solution of sublimate, and the vaseline oil is first brought to boiling point, and then allowed to cool and the calomel is previously washed in alcohol. From a half to a grain of calomel is injected at the time and the place chosen is generally the gluteal region, the needle should be pushed right into the muscular tissue. For the first few days nothing particular is observed, but at the end of a week a little nodule appears at the seat of the injection which sometimes becomes as large as a small egg, but repose and lead lotion prevents suppuration. Salivation is exceptional. M. Besnier says that four or five injections are sufficient to cure syphilis.

Chronic Itching.—The following medicinal treatment of the itching in chronic diseases of the skin is recommended:—Salicylic acid, xx grs.; oxide of zinc, starch powder, ʒv; vaseline, ℥jss.

◆

Glasgow.

[FROM OUR OWN CORRESPONDENT.]

Completion of the Glasgow Fever and Small-pox Hospitals.—The whole of the Glasgow Corporation Hospital at Belvidere, as originally planned, having now been erected, occasion was taken on Saturday last to officially inspect the institution in its completed condition. On the invitation of the Lord Provost and members of the Hospitals Committee, a large company of medical men and those immediately connected with the Corporation took part in the ceremony. The chief features of this gigantic undertaking may be thus briefly summarised:—Within the walls are two hospitals totally distinct from each other, one for the treatment of small-pox, and the other for fever patients. The former consists of five pavilions, or ten wards, capable of accommodating 150 adult patients, besides doctor's house, nurses' quarters, kitchen and stores, washing-house, stables, morgue, and other offices. The total cost of this portion of the premises has been £30,235. The fever hospital was begun in 1870, the first pavilion erected being wholly composed of wood. In 1879, contracts for four brick pavilions were entered into, and from that time till now pavilion after pavilion has been added, the wooden ones being removed to give place to the more commodious and substantial brick buildings, until there are now 13 permanent pavilions, or 26 wards, capable of accommodating 390 adult patients. The cost of the fever hospital has been £76,167. One very interesting portion of the premises consists of what is known as the Dorcas store, a large apartment which, through the kindness of a number of the ladies of Glasgow, is kept stocked with clothing for presentation to poor patients, who, on leaving the institution, are found not to be sufficiently clad. The hospital has recently been connected with the city fire brigade premises; and in order to show how promptly an outbreak of fire could be attacked the brigade was summoned by means of the electric alarm. In less than a quarter of an hour there was a body of men at the hospital with apparatus sufficient to cope with a very large outbreak of fire.

The Proposed Southern Infirmary at Glasgow.—A meeting of the inhabitants of Glasgow favourable to proceeding with the erection of the proposed Infirmary on the South Side, was held in the Merchants' Hall, on the 28th ult. The Lord Provost, who presided, said that at the first meeting of the Town Council this year an influential deputation attended for the purpose of advocating the claims of the proposed southern hospital, and to ask the sympathies of the Town Council in its behalf. This body had already marked their interest in the undertaking by agreeing to give at a very moderate rate a suitable site in the Queen's Park, and he therefore commended the proposed hospital to the favourable consideration and the liberality of the citizens of Glasgow. It seemed that though the pressure was not greater on the hospitals in the city during last year than the previous year, they were fully occupied, and it was evident that before any considerable lapse of time an increase of accommodation must take place; and surely it was reasonable and becoming that that increase which would be soon wanted should be arranged not for the enlargement of either of the important and successful institutions of which they were so proud, but that a population which numbered about 240,000, and with a natural boundary on the river Clyde, should have an hospital of their own. He could quite understand that the hospital, if erected, would produce on the South Side itself an amount of liberality which one would scarcely believe beforehand; because the duty of supporting at one's door, and the interest awakened by having an institution in the management of which one took a part, was always so very great an inducement to increased liberality that he was quite sure that the funds applicable for the carrying on of the infirmaries by the establishing of this one would be so considerably increased that neither of the two institutions already in operation would be allowed to suffer from want of funds.

◆

Edinburgh.

[From our own Correspondent.]

University of Edinburgh.—Leave of Absence to Professor Rutherford.—It is stated that Professor Rutherford, F.R.S., acting on the advice of friends, has applied to the University authorities for temporary release from duty. The immediate cause of the step is said to be ill-health, induced by over-work and worry in connection with the painful incident which has been more than once alluded to in our columns. We sympathise with the distinguished professor, and trust that the further request, implied in this step, to have the matter thoroughly sifted will be speedily acceded to by the University Court. It is understood that Dr. Caton, Liverpool, lately Examiner in Physiology to the University of Edinburgh, has agreed to take Dr. Rutherford's place in the approaching spring examinations. The arrangements for the conduct of the practical classes in summer are not yet complete.

University of Edinburgh Academic Hall.—The Government has finally agreed to make a grant of £8,000 with a view to the purchase of a site for the Academic Hall of the University of Edinburgh. The total cost of the site will be £12,000,of which the remaining £4,000 has been presented by a private donor. The building, which is expected to cost £40,000 or £50,000, ought to be one of the finest in the city. As previously stated, it is the gift of an Edinburgh citizen.

◆

THE CONJOINT EXAMINATION SCHEME FOR IRELAND.

The Irish Colleges have lost no time in acting upon the decision of the General Medical Council, who, as we have already recorded, sent back by amajority vote of 19 to 4 the Conjoint Scheme submitted by the Colleges, in order that the Apothecaries' Hall might be included in it. The Council of the College of Surgeons met last week, and by a vote of 12 to 3 passed a resolution the purport of which was that they strongly urged the College of Physicians to assent to the admission of the Apothecaries' Company to a share in the examination, but that, if that appeal was not successful, it would become necessary for the College of Surgeons to negotiate with the "Hall" for the formation of a separate and distinct conjoint examining board additional to that already contracted for with the College of Physicians. In face of the all but unanimous expression of opinion by the Medical Council, this decision was to be expected, and the hope might have been entertained that the College of Physicians would have seized the opportunity to retire from an indefensible position, and to consent to the admission of the Apothecaries' Hall to the conjunction.

It seems, however, to be a case of *non-possumus* with that sacred and reverend conclave, it being apparently of no importance to them what is best so long as their dignity is preserved. Medical Acts and Medical Councils may come and go, but the King and Queen's College of Physicians in Ireland must go on for ever in admiration of its own importance. So it has received the appeal of the General Medical Council with a vote of 19 to 2, that it will not under any circumstances conform to anybody's wish or remonstrance.

It is to be presumed that the question of a tripartite conjunction in Ireland is thus finally settled. The precipitately constructed Conjoint Scheme between the Colleges will go on, lame and impotent in its conclusion, because the College of Surgeons has rashly pledged itself, and cannot now withdraw, and there will be a second competing conjunction in Dublin qualifying at less money and, doubtless with a lower standard of examination and thus complicating Irish Medical education. But the musty dignity of a College has to be safeguarded which is a consideration supreme in importance, and the public must necessarily stand aside.

◆

At the Societies.

MEDICAL SOCIETY OF LONDON.—Monday, March 7.

Mr. Marmaduke Sheild read the notes of a very interesting case in which hæmorrhage occurred from the femoral artery and vein following suppurating buboes, and proved fatal, notwithstanding, or perhaps in consequence of, ligature of both vessels. The case evidently excited a very general interest, for Sir Wm. McCormac put in an appearance, and alluded to cases of a similar kind which he had seen. Mr. **Bernard Pitts** was enabled to record a case in which while a resident at St. Thomas's Hospital, he accidentally wounded the femoral vein while endeavouring to secure the artery. He ligatured the vein also, and the lad made a good recovery. All's well that ends well. Mr. Harrison Cripps, who published "fifty-seven cases of femoral ligature for hæmorrhage" in the Bart's Hospital Reports for 1874, advised pressure as a preliminary step to further measures. Mr. J. **Astley Bloxam** retorted by quoting two cases in which he had tried pressure, and which had terminated fatally. Mr. **Thomas Bryant**, attracted by the sound of femoral ligature, had to make the humiliating confession that he had never met with any cases of the kind. He, too, advocated pressure while the diagnosis of the source of hæmorrhage was uncertain. Mr. R. B. **Carter** referred to the celebrated Portsmouth duel case in which Mr. Liston had tied the external iliac artery for hæmorrhage from the femoral, following a bullet wound in the groin; the patient dying, nevertheless, of hæmorrhage.

It was mentioned at the general meeting that only one essay had been received for the Fothergillian medal this year, and this had not been deemed worthy.

◆

At a recent meeting of the Medical Society of London, the President, Mr. R. Brudenell Carter showed what he justly considered to be a curiosity, viz., a painting by an artist who had been rescued from total blindness by an operation for cataract. In addition to being a work of art, it derives a peculiar interest from the circumstances under which it was enabled to be produced. Successful operations for cataract are fortunately by no means rare, but a success is nevertheless a success, especially when it takes the form of a picture which being a thing of beauty will doubtless be to its possessor, a joy for ever.

TEA AS A BEVERAGE AIDING PROGNOSIS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I was glad to see in your issue of March 2nd Dr. Mortimer Granville's able advocacy of the use of tea. Having for more than half a century made tea my chief beverage, both at home and abroad, seldom taking anything more potent, I have always wondered at the ferocious attack made upon its use by various writers. When in Java many years ago, I daily consumed large quantities of the fragrant decoction, revelling uery often in teas of exquisite flavour, such as were reserved for the use of the highest Chinese nobles, the worth of some of such teas being almost fabrilous.

My well known appreciation of a cup of tea on my rounds daily caused wonder and amusement among my Chinese patients. Should I, when visiting any of their family, find in the entrance hall, a well spread table of sweets, cakes, preserved fruits, &c., and the cup that cheers but not inebriates, awaiting my arrival, I well know that the patient was markedly better and stated the fact before seeing the invalid; if, however, a solitary cup and teapot were ready for my use then I boldly asserted that the patient was in *statu quo* and cheered the friends by explaining that the fever, dysentery, cholera, &c., had not reached their Chinese, and that they must wait another day. When I entered a house and found no preparation it was at once evident that the case was rather growing worse than better, but confidence was restored by explaining I expected sad a state of things and hoped that another twenty-four hours, or as the case may be, would see a happier state of things; yet how all this was known without the patient being seen, ever remained a matter for wonder and admiration by the heathen chinee.

With regard to Dr. Granville's views as to the value of stimulants in gout, many will, I think, agree with me that they are open to grave question, certainly my own observations lead to the support of Mr. Garnett's opinion, "No alcohol no gout." *Vide* "Medical Digest," Sc., 1467 : 2.

I am, Sir, yours, &c.,
60 Boundary Road, Richard Neale, M.D., Lond.
London, N.W.

PARKES' MUSEUM OF HYGIENE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I had occasion recently to visit Parkes' Museum of Hygiene in Margaret Street for the purpose of getting some practical information on certain subjects. From the strange way in which the porter spoke and stared at me, I inferred that visitors were not common; he declared himself unable to give any information as to the whereabouts of the models I wished to see, and stated that there was no catalogue nor descriptive lists of the articles on exhibition.

Notwithstanding this unpromising reception, I entered, but only to find that the main hall was unapproachable, on account of the preparations which were being made for a tea-party. It struck me as being an odd place for a *réunion* of this description amidst models of water-closets, urinals, and drains. Fortunately the ladies did not appear in any way embarrassed by the anomalous surroundings, but they effectually prevented any systematic inspection of the sanitary marvels which are piled up on the ground floor.

I was unable to discover several of the objects I had come to see, and ultimately left, somewhat discouraged by my pursuit of science under difficulties.

Surely, Sir, some measures might be taken to facilitate the attainment of the object for which the Museum was founded. It contains a vast amount of valuable material, but partly from the want of space, and partly from a want of order and especially the lack of a numbered catalogue, these treasures can only be utilised with difficulty, or not at all.

I am, Sir, yours, &c.,
London, March 4th. W. C.

◆

THE INFIRMARY FOR CONSUMPTION—
A CORRECTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—A singular error occurs in my letter which you published last week. The amendment which was carried by the votes of the Governors at the special general meeting on the 16th ult. is not "That any attempt to limit the *liberality* of opinion and practice . . ." "Liberality" is of course nonsense; it should have been "liberty." I would now add that seven of the representatives of scientific medicine on the staff of the Infirmary have sent in their resignations, which the Executive Committee have accepted. Advertisements have also issued for one ordinary physician, three visiting physicians, and a surgeon, to fill the places vacated by the resigning medical officers. Of course the Committee will get no applications from any self-respecting members of the profession, and none but homœopaths will be likely to apply, or perhaps some degenerate members of the profession who will not object to act along with the homœopaths on the staff, and who can be little better than homœopaths themselves if they join an institution where homœopathy is openly practised, and, as the votes of the Governors have shown, cannot be excluded from the Infirmary.

But, Sir, what is to prevent all our hospitals going the same way as this Infirmary? Suppose one of the physicians of Bart.'s or Guy's were to turn homœopath, and treat his patients on that system, is there anything in the laws or constitution of these hospitals to prevent him doing so? To prevent such a catastrophe, would it not be a wise move on the part of all our orthodox hospitals to incorporate in their laws some proviso for immediately expelling any physician who should dare to introduce homœopathic remedies? Or how would it do to impose an oath on every one of the medical officers on appointment not to practise homœopathy, in the hospital, at all events, whatever they may do outside it? Ichabod! Ichabod! the glory of orthodoxy is departing from our ancient institutions! The thin end of the homœopathic wedge has been inserted in the case of the Margaret Street Infirmary. How can its further progress be arrested?

Your obedient servant,
London, March 3. A Governor.

◆

VACCINIA AND VARIOLA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Some years ago I ventured, in a paper read before the Medical Society of London, to propose to that Society that a committee should be formed containing such eminent authorities on veterinary surgery as your correspondent of this week, Dr. Fleming, and as many of the physicians and surgeons, members of the Society, as could attend, to investigate the all-important point of the identity or diversity of variola and vaccinia. My own opinion is that vaccinia must be modified variola, because: 1. It is so very rare to hear of spontaneous cow-pox in our time, when small-pox is so little seen in country districts. 2. Because Mr. Badcock told me that he had had, I think, as many as sixteen successes in causing vaccine vesicles to appear on cows which he inoculated with variola; whilst Mr. Ceely had two or three successes; Dr. Green, one; and Dr. Voigt, of Hamburgh, also one. Of course, as Dr. Fleming says, there have been many negative experiments; but that surely is not conclusive evidence. 3. Since the era of Pasteur's splendid discoveries, we can hardly conceive why vaccinia should prevent variola, unless it be "modified variola." Finally, I hold with Dr. Fleming, that "the time has long since arrived when the question should be set at rest, for it is not creditable that grave doubts should still be entertained with regard to a subject so important to mankind." Why should we not *at once* have a committee formed to investigate the point and settle it?

Yours, &c.,
C. R. Drysdale, M.D.
23 Sackville Street, London, W.,
March 3rd.

FARR'S VITAL STATISTICS. (*a*)

This is not a book which appeals to everybody, and interesting and instructive as are its contents, a special course of training is needed before most persons would derive satisfaction or information from them. Dr. Farr was a man of great but peculiar ability. His taste for matters concerning hygiene and vital statistics showed itself early in his career, but it only definitely became known to the

---

(*a*) "Vital Statistics: A Memorial Volume of Selections from the Reports and Writings of William Farr, M.D., F.R.S., &c., late Superintendent of the Statistical Department of the Registrar-General's Office, England." Edited by Noel A. Humphreys, of the Registrar-General's Office, for the Sanitary Institute of Great Britain. London: Edward Stanford.

public on the publication of his valuable article on "Vital Statistics" in McCulloch's account of the British Empire in the year 1837. In that year he first became officially connected with the then new institution for the civil registration of births, deaths, and marriages, and there are few instances of a man being nominated to a post more congenial to his tastes and talents.

One has not to read very far before one perceives that Dr. Farr's contributions to statistical science in no wise partake of the dry-as-dust character which the title might lead us to suppose. He first clears the ground by some general remarks indicative of the nature of the observations which follow, and a careful and dispassionate discussion of the results yielded by the first six censuses. His inquiries into the progressive augmentation of population and material wealth are characterised by a perspicacity and a clearness of apprehension which render them invaluable for reference on such matters, and the same remarks apply to the inquiries on marriages and births. Dr. Farr was no believer in the Malthusian theory, and he combats, by the aid of figures, arguments and inferences with a success which cannot but comfort those of his readers who only ask to be permitted to disbelieve the gloomy prophecies of that high priest of depopulation. To say that his arguments are absolutely conclusive would be rash, since the question is one which admits of more than one interpretation. Indeed, its great success and one time popularity render it extremely probable that the work of Malthus is a *reductio ad absurdam* of what is in the main a reasonable and fair speculation. The Sanitary Institute have done a great and good work in compiling the present volume, and every credit is due to the editor, Mr. Humphreys, for the patience and judgment which he has shown in the fulfilment of a task which he had undertaken. Unfortunately the technical and erudite nature of the papers, together with the price and size of the volume, render it inaccessible to many persons who would otherwise be only too pleased to become acquainted with the result of Dr. Farr's labours. It may be that at some future time an effort will be made to vulgarise the work so as to enable it to be grasped by the reader of ordinary intelligence and education. The science of hygiene is one which, to be thoroughly successful, requires the active and intelligent co-operation of every member of the community, and this can only be attained by enabling even the humbler members—from the point of view of intellectual development as well as from a mere social status—to understand the magnitude and importance of the interests which are at stake.

The volume before us is an indispensable addition to the library of everyone interested in sanitary science and the statistics on which it is so largely based. The publishers are to be congratulated on the excellent way in which the work has been produced. It is one which will remain a standard work of reference for many years to come.

◆

Medical News.

St. John Ambulance Association. — The Streatham Division of the Metropolitan Police having undergone a course of instruction in "first aid to the injured," under Deputy Inspector-General M. Coates, R.N., have been examined by Mr. G. Carrick Steet, F.R.C.S., Chief Medical Officer, General Post Office, with the result that the whole of the candidates, twenty-three in number, have been awarded certificates. This fact speaks equally well for the care and attention bestowed by the lecturer who has generously borne all the expenses himself, and pupils alike. The whole of the Lancashire constabulary, as well as the police force in several other counties, are now undergoing instruction under the St. John Ambulance Association.

The Medico-Psychological Association.—The quarterly meeting of this Association was held at Bethlem Hospital on Wednesday, the 23rd February. The chair was taken by Dr. Savage. Dr. Baker exhibited a model of a crib bedstead with a close top, as recently in use at Utica Asylum. Dr. Savage then introduced for discussion the question, "Whether there is ever sufficient reason for the use of strong clothing and side-arm dresses," which was followed by an interesting debate, in which Drs. Brushfield, Hayes Newington, S. R. Philipps, Fox, Moody, and Hack Tuke took part. The proceedings concluded with a paper by Dr. Percy Smith on "The Results of an Epidemic of Typhoid Fever in the Insane."

Health of Portsmouth.—The report of the medical officer of health and public analyst for Portsmouth to hand deals with the sanitary matters for the borough of Portsmouth for the year ending December 31st, 1886. The deaths from the seven principal zymotic diseases are 103 below the average for the preceding ten years, due principally to the comparatively few deaths from scarlet fever and measles. It is worthy of note that there has been no death from variola in the borough since 1883, and only one in that year. Several cases occurred, but by prompt removal to the Infectious Diseases Hospital, and thorough disinfection, the further spread of the disease was prevented. Whooping-cough was credited with having caused 44 deaths, and was, therefore, a more fatal disease than diphtheria. This fact is instructive. Enteric fever was more than usually fatal, 90 deaths being recorded as against 58 in 1884. Portsmouth fortunately possesses a well-arranged Infectious Diseases Hospital, the effect of which in checking the spread of disease must be immense. The report is unusually complete, and the medical officer of health is to be congratulated on the care which he has shown in its compilation.

Bequests to Medical Charities.—Under the will of the late Mr. George William Pierrepont Bentinck, J.P., D.L., formerly M.P. for West Norfolk, the following London hospitals receive £1,000 each, free of legacy duty:—King's College Hospital, St. Mary's Hospital (Paddington), Charing Cross Hospital, St. George's Hospital (Hyde Park Corner), the Great Northern Hospital, University College Hospital, the Hospital for Sick Children (Great Ormond Street), the London Hospital at the East End, and the London Homœopathic Hospital (Great Ormond Street). So as to preclude the possibility of being buried alive, the testator directs that his coffin shall not be closed or covered up for three days and three nights after his decease, and that a daily and nightly watch shall be kept during such period; and his executors are to pay 50 guineas to the person or persons keeping such watch.

Navy Medical Service.—The following is a list of the successful candidates at the recent competitive examination held at Burlington House, for appointment as Surgeon in the Royal Navy, and who have now been granted commissions:—

	Marks.		Marks.
J. D. Hughes	3255	C. Dickinson	2750
W. J. Colborne ..	3240	J. E. Coad	2745
J. H. Stenhouse ..	3180	H. Holyoake	2740
J. A. Moon	3070	G. Wilson	2700
R. Hardie	3015	J. Moore	2630
C. Bradley	2980	E. Griffin	2620
G. T. Collingwood ..	2960	J. D. Menzies ..	2615
R. Miller	2910	H. St. D. Griffiths ..	2550
G. F. Collins	2810	W. Bowden	2510

Indian Medical Service.—The following is a list of the candidates for Her Majesty's Indian Medical Service, in the order of merit, who were successful at the competitive examination held at Burlington House on the 14th February and following days:—

	Marks.		Marks.
Meyer, C. H. C. ..	3485	Fisher, C. G. ..	2995
Elliott, W. A. W. ..	3340	Buchanan, A. ..	2970
Childe, L. F.	3320	Manifold, C. C. ..	2905
Clark, W. R.	3 90	Jacob, A. H.	2900
Braide, G. F. W. ..	3270	Garvie, J.	2890
Murray, J.	3230	Jolliffe, A. R. ..	2880
Hailey, P. O. W. ..	3160	Crawford, F. J., M.D.	2770
Marks, R. J.	3150	McEvoy, W. G. ..	2760
Ker, M. A.	3100	Macleod, H. W. G. ..	2760
Barry, T. D. C. ..	3040	Robertson, R. ..	2750
Gilbert, C. E. L. ..	3040	Irvine, G. B.	2730
Vost, W.	3040	Moore, T. C. .. .	2730
Herbert, H.	3035	Karney, W. H. ..	2720
Sunder, C. E. ..	3000	Simpson, D.	2720

73 candidates competed for 28 appointments; 70 were reported qualified.

King and Queen's College of Physicians.—The following candidates passed at the February meetings of the Examiners at this College:—

Medicine.

Butler, James
Egan, James Davis
Foley, Thomas McCraith
Freebour, James S.
Frood, Thomas Morton
Hamilton, W. Richard George
Nash, Vincent

Midwifery.

Egan, James D. | O'Sullivan, E. F. | Nash, Vincent

Membership.

Lyster, Patrick Thomas | Stone, Ralph

Notices to Correspondents, Short Letters, &c.

☞ **CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attenion to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

DR. WM. SQUIRE.—We hope to find space for a consideration of the subject in our next.

THE ORPHANS AND WIDOWS OF MEDICAL MEN.

WE are asked to announce that relatives of deceased members of the "Society for Relief of Widows and Orphans of Medical Men" wishing for pecuniary assistance must apply for and send in the necessary forms of application before the 22nd inst. to the Secretary, 53 Berners Street, London, W.

MR. GRESSWELL (Lincolnshire).—Your letter shall be kept in mind.

SANITARIAN.—There is no better work than *Parkes's Hygiene*. "To get your country clean, and your people lovely, I assure you (says Ruskin) that that is the necessary work of art to begin with." Cleanliness is indeed next to godliness.

A **PERPLEXED AUNT.**—With great respect, your old nurse is miserably ignorant, and what you propose would be a useless, unheard of and stupid proceeding. Whether or not it has been ever done we know not but we are quite positive that "nice people" have never thought of such a disgusting mutilation.

DR. LAFFAN.—We could not possibly afford space to transfer to our columns your communication to the Medical Council as to the Royal University. We agree with you that the Reports of the Visitors on its examinations and those of Dublin University deserved much more attention from the Council than they received, but on the question of recognition of workhouse hospitals, you already know our views.

DR. GODWIN TIMMS.—"Notes on the After-Treatment of Diphtheria, with Cases" received.

UNQUALIFIED PRACTICE.—A WANT OF CONSISTENCY.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—In the annotation headed "A Want of Consistency" in your last number you call attention to a state of things which has long struck many of us as anomalous in the extreme. It is as if a religious journal abused atheism in the editorial department and advertised Freethinking works in another part. All the medical journals join hands in deprecating the employment of unqualified assistants, especially for branch practices, yet none of them (with the exception of your journal) have the courage of their opinions sufficiently to refuse advertisements of this kind. The old excuse about the separate identity of the editorial and advertisement departments may be convenient, but is absurd as an argument, and inadequate as an explanation. The editor knows how to prevent the advertisements of the works or institutions of heterodox practitioners appearing, and there is no reason why the veto should not be extended so as to include what they affect to condemn. The "almighty dollar" is as powerful here as elsewhere, and the editorial soul is evidently accessible to considerations of a financial character, even if consistency and professional etiquette have to suffer in consequence.

I am, Sir, yours, &c.,

KUDOS.

◆

Meetings of the Societies.

WEDNESDAY, MARCH 9TH.

EPIDEMIOLOGICAL SOCIETY OF LONDON.—At 8 p.m., Dr. S. Mackenzie (for Dr. W. Myers): Filiaria Sanguinis Hominis in South Formosa.

HUNTERIAN SOCIETY.—At 8 p.m., Dr. Horrocks: Cases of Uterine Tumour accompanied by Pyrexia. Dr. Turner: Actinomycosis.

ROYAL MICROSCOPICAL SOCIETY.—At 8 p.m., Mr. G. Massee: On the Differentiation of Tissues in Fungi. Dr. H. J. Johnston-Lavis and Dr. G. C J. Vosmaer: On Section-cutting of Sponges, &c.

BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 p.m., Exhibition of Specimens. Dr. Purcell: On Three Cases of Vaginal Hysterectomy.

THURSDAY, MARCH 10TH.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At 5 p.m., Dr. MacAlister: The Nature of Fever (Gulstonian Lecture).

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—At 8.30 p.m. Living and Card Specimens at 8 p.m.:—Dr. C. E. Beevor: Ophthalmoplegia Externa without any other symptoms. Dr. Sidney Phillips (introduced): Case of Peculiar Associated Movement of Upper Lid. Mr. Brudenell Carter: (1) Case of Large Spontaneous Hæmorrhage into the Vitreous in a young man: (2) Painting executed by an artist after Cataract Extraction. Mr. J. G. Mackinlay: Paralysis of both External Recti. Mr. Karop (introduced): Fibroid Degeneration of Ciliary Muscle. Mr. Marcus Gunn: Pupillary Movement in Association with Lateral Deviation of Eyeballs. Papers:—Dr. Brailey and Mr. Hartley: Tubercular Disease of Choroid. Mr. Simeon Snell: Treatment in Sclerotic Wounds. Dr. Gowers: On Conjugate Ocular Palsy with Nystagmus. Mr. Jessop: Sudden and Lasting Lateral Nystagmus. Mr. Nettleship: Night-blindness with Peculiar Retinal Changes.

FRIDAY, MARCH 11TH.

CLINICAL SOCIETY OF LONDON.—At 8.30 p.m., Dr. de Havilland Hall: On Pneumothorax occurring in Persons apparently Healthy. Mr. Eve: On a case of Intra-peritoneal Excision of the Rectum, with recovery. Mr. Keetley: A case of Scoliosis. Mr. Davies-Colley: A case of Contraction of the Metatarso-phalangeal Joint of the Great Toe.

ACADEMY OF MEDICINE IN IRELAND.—The Medical Section will meet in the College of Physicians at 8 p.m.—(1) Report of Reference Committee on Lower Limbs of a Fœtus exhibited by Dr. Macan. (2) The President: Malignant Disease of Stomach, Pancreas, &c. (3) Mr. A. H. Benson: Fibroma Corneæ. (4) Mr. McArdle: Sarcoma. (5) Dr. M. A. Boyd: Perforation of Stomach. (6) Mr. Wheeler: Description of Calvarium and Brain after Trephining for Epilepsy. (7) Mr. H. R. Swanzy: Coloboma Iridis and Aphakia. (8) Mr. J. A. Scott: Fatty Substitution of Erector Spinæ in the Pig. (9) Dr. E. H. Bennett: Malformation of Shoulder-joint. (10) Dr. C. B. Ball: Gonorrhœal Arthritis.

Vacancies.

Derbyshire General Infirmary.—House Surgeon. Salary for the first year £100, increasing £10 a year up to £150, with apartments, board, and washing. Applications with testimonials to be sent to the Secretary, not later than Saturday, March 26th.

Hastings, St. Leonards, and East Sussex Hospital.—House Surgeon. Salary £70 per annum, with board, lodging, and laundry expenses. Applications with testimonials, to be sent, on or before the 25th inst., to the Secretary.

Holborn Union.—Medical Officer to the Workhouse at Mitcham. Must reside near establishment. Salary £100, drugs and medicines found by Guardians. Applications with testimonials to Clerk's Office, before twelve o'clock noon on Tuesday, the 14th inst. (See Advt.)

Male Lock Hospital, 91 Dean Street, Soho.—House Surgeon. Salary £50 per annum, with board and lodging. Applications with testimonials must be sent on or before 15th March, at noon, to the Secretary, Lock Hospital, Harrow Road, W.

Medical Officer of Health for the Parish of Putney.—Salary £75 per annum, rising (subject to the order of the Board of Works for the Wandsworth District), by annual increments of £5 each to a maximum of £110 per annum Applications must be delivered at the offices of the Board, Battersea Rise, not later than Monday, the 21st day of March inst.

Stockport Infirmary.—Assistant House Surgeon. Salary £70. Applications to the Honorary Secretary on or before March 15th.

Appointments

BRANSON, J., L.R.C S., M R.C.P.Ed., Medical Officer for the Rotheram District of the Rotherham Union.

COLE, W. R. N., M.D., M.Ch. Queen's Univ. Irel., Medical Officer for Seventh District of the Bodmin Union.

Original Communications.

THE NEUROTIC.

By J. MILNER FOTHERGILL, M.D.,

Physician to the City of London Hospital for Diseases of the Chest.

A WAXING experience of practice as a medical man brings with it many lessons. Among others one important matter it teaches, and that is, the essential difference betwixt individuals. They are different in build, and equally unlike in temperament. This is broadly seen in the comparatively large bulk of country people as compared to town populations. See the massive men encountered at Carlisle on Market day, with their mighty thews and sinews; and contrast them with the slight beings encountered in Whitechapel. The effect of town-life is to dwarf the physique. In the production of the result several factors are in action. The want of exercise in the fresh air, and with that a deficiency of oxygen is certainly one matter. The amusements of a rural population are mainly conducted in the open air; while the amusements of town residents are mainly in doors with a very impure atmosphere. Then the excitement of town life leads to a rapid and precocious development of the nervous system, which tells injuriously upon the nutritive powers of the system. In other words the rapid development of the medullary portion of the epiblast taxes the capacities of the mesoblastic structures on which the epiblastic structures rest for their nutrition. I may remind the reader that the epiblast or outer layer supplies the nervous system and the epidermis; the hypoblast or inner layer, the glands along the alimentary canal; while the mesoblast gives the bones muscles, vascular system, genito-urinary organs, and the other tissues of the body. While there is a certain antagonism apparently betwixt the epiblastic and hypoblastic tissues; and precocious nervous development goes on hand in hand with impaired efficiency on the part of the glandular elements of the digestive organs derived from the hypoblast. Puberty too comes swiftly upon the immature organisms, and brings with it further demands upon the nutritive powers. The consequence of one thing and another is, that urban populations are physically inferior to rural populations. The stalwart country man enters a town and settles down there. His descendants grow smaller till they die out, unless reinforced by draughts of fresh country blood. Probably, however, if the puny town dweller were restored to the country his children would expand.

But as a matter of fact, in the country, there are differences even in the members of the same family. Some are large, others are small. Speaking broadly one will present the stalwart figure of a Norseman, while the other has the slighter framework of an Arab. This latter is the neurotic member of the family group. Why the various children should thus differ is hidden from us; but the fact remains. Of course there is a wide distinction betwixt this neurotic of good family history in the country, and the degenerate neurotic of Shoreditch. Both are neurotics all the same, with the characteristics of neurotics. It is the difference of individuals of families. While the difference of the neurotic from the Norse type is that of races—of the small dark descendants of the Cymri and the larger fair descendants of the Norseman. The class of neurotics may be subdivided into the (1) healthy neurotic; (2) the degenerate neurotic; and (3) the strumous neurotic. But for the present consideration the class will be regarded as a whole.

The tendency of town life is to determine the physique towards the neurotic type, as may be seen by contrasting the small dark beings of the living crowd at Madame Tussaud's with the larger fairer personages who are to be seen represented there by *facsimiles;* or by taking a tour round the picture galleries of Hampton Court Palace and comparing the present generation with the past. And as town dwellers are now the majority of the population, the neurotic comes before the physician with recurring frequency. Consequently the peculiarities of the neurotic are of growing importance to the medical man.

A typical neurotic will complain of indigestion, with acidity and flatulence; more or less constipation; of migraine accompanied by vesical irritability; of palpitation, or of anginal attacks, or failure of the heart's action, which differs from syncope in that there is no loss of consciousness. On questioning a neurotic, and still more a female neurotic, it will be found that there is a history of sediments in the urine. Not uncommonly, there is also a history of some skin trouble or other. She usually has dysmenorrhœa, with a scanty loss, and often complains of rheumatism, while most female asthmatics are of a neurotic type.

Here are a distinct series of phenomena presented in more or less entirety, along with the slight bird-like figure of the typical neurotic. If the neurotic be of a goodly size and stature, it is not unusual to see gouty affections of the joints or even eczema. Indeed, in a very large proportion there is a distinct tendency to revert to the uric acid formation, normal to the bird and reptile. We see that the description commences with troubles referable to the digestive organs, and this is a matter of considerable interest in conjunction with the uric acid formation. A neurotic may have primary uncomplicated atonic dyspepsia, or, in other words, a feeble stomach. But more frequently the dyspepsia is accompanied by acidity and flatulence, often alternating. When this last is the case, there is almost invariably a history of lithates in the urine. What are the relations of the two? We have become so accustomed to associate this uric acid formation (otherwise gout poison) with excessive consumption of food, and largely animal food, that "poor man's gout" is apt to be lost sight of. But a little consideration of the subject will teach us that the consequences of a capable liver chronically overtaxed, and of an incapable liver burdened by a normal and moderate dietary, will be the same: viz., the reversion of the liver to the uric-acid formation. The bird and the reptile pass a solid urine consisting of urates. The mammalia have a fluid urine with the soluble urea as their form of nitrogenised excretion. But traces of the uric acid formation cling to the most perfect mammals, even to the Bimana. The inheritance remains, and, when the liver is burdened, it reverts to the earlier primitive uric acid formation, whether as "rich man's gout" or "poor man's gout." The congenitally "insufficient liver" was recognised by Dr. Budd; and Dr. Murchison endorsed the view ("Functional Derangements of the Liver,") that some persons come into the world with defective livers, incapable of much labour. Such a person is liable to bilious attacks with frontal headache, furred tongue, bad taste in the mouth of a morning, with bilious vomiting, or purging following upon constipation. Such is the bilious neurotic as compared to the dyspeptic neurotic. The bile acids both contain nitrogen, and one also contains sulphur. This chemical fact points to their descent from the albuminous elements of the food. The bile acids and the uric solids have a common ancestry. And the neurotic who is bilious in early years, commonly becomes gouty in middle age. It is the albuminoid elements of the food which burden the liver. Dyspepsia and bilious attacks are the protectors of the incompetent liver. The child who over indulges in rich food (of old called a "surfeit,") pays the penalty in the form of a bilious attack.

But usually kindly dame Nature when sending a child into the world with an insufficient liver, protects this feeble viscus by endowing the child with a small appetite. It is a small dainty, fastidious eater, much to the chagrin of its nurse. It grows up either suffering from bilious attacks, or it suffers from indigestion. Vain are all the attempts to improve it by "feeding it up." It simply cannot be fed up! All attempts to do so are frustrated by the liver; which, instead of dealing satisfactorily with the increased amounts of food borne to it on the current of the portal vein, falls back or reverts to the uric acid formation. When the liver is embarrassed loss of appetite follows, and the food supply is cut off till the liver comes round again. To give tonics and bitters to improve (?) the appetite is to thwart Nature's processes, and to intensify the tendency of the liver to fall back or revert to the uric acid formation in one case; and to increase and multiply the bilious attacks in the other. Nature will manage much better if left alone than when meddled with injudiciously. Many neurotics, especially ladies, have related to me their sad experiences from attempts to feed them up.

Many, too, and especially American ladies, have given vivid accounts of the hard work and energy displayed by their fathers. Long mental toil tells upon the liver; especially in stoical undemonstrative persons, as seen in the production of diabetes and the vaso-renal change, commonly spoken of as "Bright's disease." This fact is one more instance of the truth underlying the statement—"The fathers have eaten sour grapes, and the children's teeth are set on edge." The fathers impair their digestive and assimilative organs (the tissues of the hypoblast) by mental toil, and their children come into the worlds with insufficient livers. Again, it is the story of the epiblast preying upon the hypoblast. The child possesess a bright brain and a crippled liver.

These neurotics are liable to have attacks of hemicrania or migraine. The pain is temporal, and through the eye; and almost always unilateral, but very rarely on the left side. Commonly, the pain shoots through the eye, and sparks, or lines of light are seen. Often the attack ends in vomiting. One curious association of migraine is vesical irritability. There is a constant call to empty the bladder; and frequently a considerable quantity of pale urine is voided, but not necessarily so; sometimes a larval attack occurs with mere mental irritability and the vesical trouble, without the physical pain.

In many of these dyspeptic neurotics can be found the tight artery, the large left ventricles with loud second sound, and the copious urine of the vaso-renal change But usually this condition of the urine alternates with that of a small bulk of urine loaded with lithates. Renal changes, and especially cirrhosis or insterstitial nephritis (Boyle's disease) are found in time.

Such a neurotic is rarely the mother of a large family; and when she is multiparous she lives in the country. The urban neurotic is commonly sterile. Probably the reason of this is imperfect reproductive organs. Irritable and tender ovaries are common among them, and this condition may interfere with perfect ovulation, the ova never becoming fully developed. The uterus is commonly small and infantile, and impregnation frequently results in abortion. Her child, when she has one, is small and delicate, and rarely survives the maladies of childhood. It is a bright-brained little fairy, "too good for the world," upon which it soon turns its back, to the regret of all.

The neurotic is liable to palpitation, and to curious attacks of failure of the heart's action which are very alarming; but which, to the best of my knowledge, are not really serious. In fainting, or syncope, consciousness is lost; but in these attacks the sufferer is acutely conscious of intense mental pain. From the association of flatulence the neurotic dyspeptic experiences a good deal of sharp pain in the region of the heart, and referred to that organ. It is really wind pouched in the angle where the transverse colon curves downwards. As the elastic gas presses the heart through the thin diaphragm and causes it to beat irregularly, the association of the pain with the heart is convincing to the sufferer; who believes the heart to be the seat of actual disease. And this is not unfrequently the particular matter for which the physician is consulted. So strong is the impression on the mind of the sufferers, that sometimes it is somewhat difficult to convince them to the contrary.

The healthy neurotic is a small, active being of ceaseless industry; indeed, a typical example of the adage "the sword will wear out the scabbard." Neurotic ladies use up every particle of energy, and then go to bed to recruit. Headache is the penalty of over-exertion, but it constitutes no lesson. (If those who only see the neurotic bright and fascinating, when well enough to be outdoors and in society, could see her in her hour of suffering, they would be less pressing in their attentions to her, and better comprehend the difficulties of her natural guardians in trying to take care of her.) Knowledge does not inspire conduct. They can take care of anyone but themselves. Usually of high intelligence, they are incapable of foresight in the matter of "knocking themselves up," as the popular term goes. They are often unselfish, and do themselves a great deal of injury in devotion to some good object.

The degenerate neurotic of towns is usually a voluble agitator and spouter, teetotaller and vegetarian, when a man; as a woman, she is fidgetty, "all up and down," as her friends describe her. When the degeneracy assumes a strumous aspect, it commonly takes the form of joint-disease. And most of the children we encounter in the streets minus a limb belong to this class. Such children have generally a family history which tells of one or more of the number having died of hydrocephalus in infancy, or of phthisis later on. Even when flighty, excitable, and moodish, the neurotic is not so liable to hysteria as girls of the lymphatic diathesis, in whom the nervous system is defective.

The neurotic dyspeptic is usually a very pleasant patient, grateful for small mercies. It is difficult to get her (when a lady) to follow out a proper dietary in consequence of her self-forgetfulness, and her dislike to have food specially prepared for her. While as for medicinal measures, the neurotic dyspeptic is the most difficult patient to treat satisfactorily of all those who seek the physician's help.

Clinical Lecture

ON

THE TREATMENT OF TYPHOID FEVER. (a

By Professor H. NOTHNAGEL,

Vienna.

(*Continued from page* 2.6.)

I have already mentioned that increased tissue metamorphosis takes place in fever, and at the cost of the

---

(a) A Lecture delivered in the Medical Klinik of the University of Vienna, January, 1887.

bodily substance which is burnt up in the process. Now, alcohol is a substance that oxydises, undergoes decomposition, more readily than other body material, such as albumen, fats, hydrocarbons, that are found in the cells and tissues of the organism. When we introduce alcohol into the system in large quantity the heightened tissue change takes place first of all at the cost of the alcohol, a substance that is readily attacked by the oxydation processes, and thus the body tissues are spared. In this way alcohol acts indirectly as a food for the preservation of the organism. This view appears to be correct. We have thus two indications for the administration of alcohol in acute febrile diseases, first as a cardiac stimulant, in weakness of the organ; second, as a sparing agent against the tissues changes which are heightened. If you hold fast to these principles you will at once arrive at decided, firmly based, scientific views as to the cases in which we give alcohol in acute febrile diseases. I am decidedly opposed to the promiscuous exhibition of alcohol, without discrimination in all acute febrile diseases. I am therefore, opposed to giving alcohol in every case of pneumonia; only one indication demands the administration of alcohol, that is weakness of the heart, when this developes in pneumonia we must give it. On the other hand, pneumonia is a disease with a short febrile course of seven to nine days; this short duration of fever does not bring patients so low that you must give alcohol for it. The same holds good with regard to similar affections with a short fever course, for example, typhus recurrens, &c. But it is a different matter with typhoid fever, in which we have to deal with a long continuing febrile disease, then not only does the indication of cardiac weakness come into consideration, but we have to take into consideration also the question of preserving the bodily substances, and for this reason it is demanded in typhoid, and it is necessary and requisite to give wine in all cases without exception from the first. From the first day on which you determine your diagnosis of typhoid give wine as a sparing agent. The quantities that can be given are positively incredible. I have seen that delicate ladies, who have not been accustomed to wine, have taken in a day a whole bottle of wine (three-fourths of a litre containing ten per cent. of alcohol), twelve to sixteen coffee spoonfuls of brandy, and beer in addition, and what is remarkable, the brain was not acted on. An immense quantity of alcohol must have been given for fever patients to get any sort of drunkenness, any action on the sensorium; the alcohol in these conditions is burnt off so rapidly that it scarcely affects the cerebral activity at all. As for the wine that you given such patients it matters little whether it is very good, the only thing is that it contains alcohol. For this reason in all these cases you may give any of the imported wines that go under the names of Malaga, port wine, Cape wine, Madeira, &c. I say the wines that go under these names for I cannot undertake to be responsible that these wines in question are really grown there. The wines are prepared by the addition of alcohol, spirit, sugar, &c., in these cases, however, it does not so much matter if they only contain alcohol. Then with us patients are given good, heavy Hungarian wine, Dalmatian wine, &c., the aroma and the taste are of no consequence. Whether you give red or white wine I hold to be irrelevant. It is believed that red wine constipates, and white wine relaxes the bowels. This is immaterial, the white wine relaxes so little that we give it in typhoid with perfect calmness, and red wine constipates so little that we could not cure a diarrhœa with it.

We come now to the second indication, the combatting of the fever. I would premise that our views on the treatment of fever have materially changed, with regard to the opinion as to the significance of the fever. When you take the earlier handbooks in your hand, for instance, the very excellent handbook of Griesinger on infectious diseases, you will there find the expression that standing at the bedside of a typhoid patient one is animated by the wish solely to reduce the fever. When Griesinger wrote that about thirty years ago, we were not yet in a position to reduce the fever with certainty. Nowadays, we have the power in a quite remarkable manner, and we have advanced a little further than this, but not so much so as Griesinger has thought. In earlier times the fever was held to be a highly noxious thing, in the times when Griesinger wrote that, and later when the antipyretic method was brought into the foreground. Before that period there was a time when the fever was looked upon as something useful, and now we again recur in a moderate degree to this view, that we do not view the fever as something that must be combatted unconditionally and at any cost, but as a symptom that has its complete justification, and if you will, even its therapeutical value, I will not enter upon this question, I will only point out the following:—We see that there are febrile diseases, accompanied by considerable rises of temperature, in which the patients do not suffer much, I mean in which the organism does not indicate any considerable disturbances. There is, for example, the pyrexia which we observe in the course of recurrent fever, one of short duration, in which we have no disease of any internal organ that is dangerous to life. Erysipelas affords an example that a fever may last ten to fourteen days, the patient not being particularly injured by it, although a certain injurious influence is exerted by the febrile rise of temperature upon the nutrition of the cells of the organs, that is not so important that the fever must be attacked unconditionally. On the other side, observation has taught us that reduction of the temperature *per se* does not render the course of the disease more favourable. I have already told you that by the steady employment of thallin it is possible to keep a case of typhoid completely, or almost, apyretic, and yet we do not see that the course of the disease as a whole, is shortened thereby, that the symptoms are really improved. Thus the banishment of this one factor alone out of the whole group of symptoms does not influence the course of disease. This is the striking proof that our aim in the acute febrile diseases is not to combat the fever, but to seek out specific remedies. If we knew a specific remedy that would at the same time destroy the virus of the disease, the matter would take on a different aspect, but the taking away of this one factor from the whole group of symptoms does not lead to the desired result. On the other side, observation at the bed-side appears to teach, and we have certain data in favour of this from the life histories of the micro-organisms, that to a certain extent a febrile rise of temperature is a remedial agent, that with the heightened temperature the symptoms run a quicker and more favourable course than when fever is absent. The views that are held at present by the majority of German clinicists on the treatment of typhoid I may group together in the following:—A decided antipyresis is necessary in hyperpyrexia, it is unconditionally demanded in typhoid when the morning and evening temperatures keep above 40° (104 Fahr.) and when decided symptoms are present on the side of the nervous system. So long as patients have a free sensorium with a morning temperature of 39° C., so long as the pulse is distinct, the cardiac function is properly performed, antipyresis is not unconditionally demanded; if you treat your cases antipyretically you do no harm, but at the same time you do not do much good. These are about the principal rules according to which we act. For the accomplishment of the antipyresis there are various ways at our command. We divide antipyretis into two great groups, into remedies that reduce temperature chemically, chemical antipyretics, and those that reduce temperature by abstraction of heat. The chemical remedies have become uncommonly plentiful during recent years. Formerly quinine was the only chemical antipyretic we knew. Along with this various other remedies were employed, such as digitalis, which was often mentioned as an antipyretic in the fever literature of the fifties and sixties. Wunderlich, Thierfelder, and Traube also used digitalis. The acids were also given then as antipyretics, nitrate of potash, nitrate of soda, &c. Of all these remedies quinine is the only one remaining, everything else is abandoned. The other antipyretic remedies were ranked along with quinine. Veratrin was the first to be received in this relation. This had only an ephemeral existence, it reduced temperature, but caused the most serious symptoms of collapse, and veratrin is to-day quite abandoned as an antipyretic. By the side of veratrin was placed resorcin, this reduced temperature very energetically, but it had the same disadvantage as veratrin in causing serious symptoms of collapse. Then another antipyretic was introduced that retained its place more securely, that is salicylate of soda. Then came the remedies discovered synthetically, of which the first to be named is that introduced by Filehne, kairin, which, however, had only a short epoch, two to three years, as it also possessed serious disadvantages, it reduced temperature, but with pronounced symptoms of collapse. In the last few years we have become acquainted with new antipyretic remedies, first of all thallin, introduced by Dr. von Jaksch, then the antipyrine of Filehne, and lately antifebrin from Kussmaul's klinik. I will not describe all these remedies in detail, but will mention the following in general terms:—The importance and effectiveness of the antipyretics in febrile conditions I shall at present leave untouched, quinine, for example, acts quite differently in typhus, recurrent fever, and erysipelas, from what it does in typhoid; in those affections it scarcely acts at all, whilst in typhoid it is a good antipyretic. What I am going to say regarding the three remedies mentioned just now relates only to typhoid. In this disease only quinine and salicylate of soda come into consideration on one side, and on the other thallin, antipyrine, and antifebrin.

There are certain views that must force themselves in advance on the attention of the scientifically thinking physician. I will make this clear to you by an example. When chloral was introduced into medicine in 1869 by Liebreich expression was given to the view that it was an absolutely harmless medicine, that it produced sleep without causing any injurious bye-effects. When one is accustomed to think physiologically one could and must say to oneself, when a remedy of that kind acts on the ganglion cells of the central hemispheres so as to force on a deep sleep, the remedy must, under certain conditions, be liable to act injuriously. For you know that the alkaloids, the chemical active substances act not alone upon a single organ, but upon the whole organism, they are carried with the blood to every part. When you give digitalis this acts not upon the heart alone, but also upon the brain and various systems of nerves of the stomach and intestines; opium acts not on the brain alone but upon the heart, upon the vaso-motor centres and the various other systems of nerves; strychnine acts not upon the spinal cord alone increasing the reflex excitability, but it is an intensive stimulant for the vaso-motor centres and acts finally upon the brain and the other nervous apparatus, the same is repeated with atropine, veratrin, and all other substances. When we employ a definite remedy therapeutically for a definite purpose, for example, when we give morphine as an anodyne and hypnotic we do so because the remedy indeed acts generally upon the whole organism, but its principal action unfolds itself upon a definite group of nerve and ganglionic cells. We designate this property as specific affinity. Without doubt this action on the alkaloids comes to pass by their direct action on the substance of the ganglia or the nerve fibres. Digitalis acts upon all nervous apparatus, but with special intensity, and in the first instance upon the nerve apparatus that regulates, or presides over the heart. We can utilise this action therapeutically in the treatment of cardiac diseases, we get the action upon the cardiac nerves, without its action upon the other apparatus coming into force. The art of clinical observation consists in finding out the doses that act just as we wish upon definite apparatus, but at the same time not upon the other nervous apparatus. I have made this excursion in order to point out to you how you should comprehend the action of remedies. To return to chloral, one was able to say in advance: a remedy that acts so intensively upon the cerebral cortex, must under certain conditions also possess the power of paralysing the grey nuclei, the respiratory centre, and the ganglionic cells of the cardiac centre, *i.e.*, that under certain conditions it will attack the vital nerve apparatus, and if too large doses be given, or if an individual have a special susceptibility it may under certain conditions act injuriously. Further observations have abundantly demonstrated this, we have now a large series of fatalities caused by chloral, where chloral has paralysed the vagus centre, the respiratory and cardiac centre, and has thus not acted exclusively upon the cerebral cortex.

(To be continued.)

◆

REMARKS ON THE RESPIRATION OF ASCENDING AND DESCENDING RHYTHM. (*a*)

By HERBERT C. MAJOR, M.D.,

Physician to the Bradford Infirmary.

The remarkable variation of the normal respiratory process termed by the late Dr. Stokes, of Dublin, the respiration of ascending and descending rhythm, and now commonly known as Cheyne-Stokes respiration, while not by any means a commonly occurring symptom is probably well-known to all of us who have at one time or another encountered it at the bed-side. We know that the characters of the phenomenon are, when fully developed, most striking and peculiar, so much so as to arrest the attention of a non-medical observer, while for us the symptom has an interest and a significance all its own. And because of this, because of the great importance of the symptom in any case, and of the mystery which still surrounds its causation, I have thought that a few remarks with regard to it might not be considered useless or out of place this evening.

No lengthy general description of the phenomena is, of course, called for. Perhaps, however, I may quote as being of historical interest the first descriptions of Dr. Cheyne and Dr. Stokes, which for directness and accuracy, as far as they go, cannot probably be surpassed. Writing in 1816, of a patient under his care, 60 years of age, who laboured under fatty degeneration of the heart. Dr. Cheyne states:—"His breathing was irregular for several days; it would entirely cease for a quarter of a minute, then it would become perceptible though very slow; then by degrees it became heaving and quick, and then it would gradually cease again. This revolution in the state of breathing occupied about a minute, during which there were about thirty acts of respiration." Dr. Stokes' original description is as follows:—"It consists (he says) in the occurrence of a series of respirations, increasing to a maximum and then declining in force and length until a state of apnœa is established. In this state the patient may remain for such a length of time as to make his attendants believe that he is dead, when a low inspiration, followed by one more decided marks the commencement of a new ascending and then descending series of respirations." He adds—"I do not know any more remarkable or characteristic phenomena than those presented in this condition, whether we view the long cessation of breathing without any suffering on the part of the patient, or the maximum point of the series of inspirations when the head is thrown back, the shoulders raised, and every muscle of inspiration thrown into most violent action; yet all this without any rate or sign of mechanical obstruction."

(*a*) Read before the Bradford Medico-Chirurgical Society at the February Meeting.

I will only refer by way of further description to the account of the symptom given by Guttmann in his well-known "Hand-book of Physical Diagnosis" (New Syd. Soc. "Trans."), in which he deals more precisely with the duration of the stages of the altered rhythm. He states that in the most pronounced cases the dyspnœal period comprises about 30 respirations, and occupies ½—¾ of a minute, while the pause or apnœal period is of nearly the same duration; the whole cycle of phenomena, therefore, taking up 1—1½ minutes. In less marked cases, he adds, the cycle lasts only about ¼ minute, and may then be easily overlooked, especially when the pause is very short.

It may not be amiss to mention here a peculiarity of the breathing sometimes observed which it is very important, I think, we should never confound with Cheyne-Stokes respiration properly so-called. In the words of Broadbent "when a person, especially one advanced in years, is lying on his back in heavy sleep and snoring loudly, it very commonly happens that every now and then the inspiration fails to overcome the resistance in the pharynx, of which stertor or snoring is the audible sign, and there will be perfect silence through two, three or four respiratory periods; finally air enters with a loud snort after which there are several compensatory deep inspirations before the breathing settles down to its usual ryhthm." Probably, however, we shall agree that not only in natural sleep is such a series of events familiar to us, but that often also in apoplexy, anæsthetic narcosis, and states of coma generally, is it liable to be observed.

Passing now to the consideration, as far as circumstances will permit, of the various classes of cases in which Cheyne-Stokes respiration has been observed and recorded, we may remember, to begin with, that Stokes, in 1846, first urged its significance as a sign of fatty degeneration of the heart, believing that its presence was pathognomonic of this affection; and this view was naturally, coming from such an authority, widely accepted. It was soon negatived, however, by Dr. Seaton Reid who described a case in which the muscular substance of the heart was found healthy, there being, however, incompetence of both aortic and mitral valves, hypertrophy of left ventricle and dilatation of aorta.

Dr. Hayden found dilatation with loss of elasticity of the aorta in all the cases which he studied, and was led to the conclusion that such a condition was constantly associated with Cheyne-Stokes rhythm. Von Dusch in 1867, asserted that he had observed the symptom in certain cerebral affections, tumours of brain, basal meningitis and uræmic coma. I may next refer to a remarkable case which came under observation at the Hotel Dieu at Lyons, in 1876. The patient, a man, exhibited the phenomenon in a well-marked form for a period of 29 days, when death ensued. The case was reported at length in the Lyons *Medical*, 1876, by M. Biot, and reference to it will be found in the *Lancet* for February 17th, 1877, where also there is allusion to the experience of V. Dusch, to which I have already referred. Physical signs during life had disclosed undoubted aortic incompetence in this case and there was considerable atheroma of the peripheral arteries (and presumably of the aorta also), but, unfortunately, a post-mortem examination could not be obtained. Dr. Broadbent (*Lancet*, March 1877) describes two cases of cerebral apoplexy in which the Cheyne-Stokes respiration was distinctly noted; in one of the cases the patient, notwithstanding, recovered, while in the other instance, although the patient rallied from the seizure death occurred ten days later, in a subsequent attack. Broadbent also testifies to the occurrence of the symptom in uræmia. He observes that he is unable to say of all the cases so associated that there was always change in the heart and aorta, but that of course kidney disease tends to this. He adds his opinion that the one fact respecting the phenomenon which appears to be common to almost all the cases is loss of elasticity and dilatation of the aorta to which Hayden first called attention. Dr. R. Wharry (*Lancet*, March 1877), gives five cases in his own experience, viz.:—1. In a patient with mitral constriction and dilated aorta. 2. Patient with double aortic disease and mitral regurgitation. 3. In a child with acute nephritis and uræmia, following scarlet fever. 4. In a case of typhoid fever complicated with pneumonia. The last-named case, of which a full account will be found in the *Lancet* for March 17th, 1877, made a good recovery. Other instances of the occurrence of the symptom in apoplexy, might be adduced, among these one recorded by Mr. W. A. Frost, in the *Lancet* for August 18th, 1877. In this case there was found marked degeneration of the vessels of the brain, but the state of the heart could not be ascertained.

I have been able to find but little record of Cheyne-Stokes respiration occurring in children. That it does so occur is certain, however, especially in acute hydrocephalus. Von Dusch, as previously quoted, gives "basal meningitis" as one of the affections in which he observed the symptom. In his lectures on the "Cerebral Fever" of children, Trousseau alludes to it as being most significant in the diagnosis of that affection. His words are (New Syd. Soc. "Trans."): "You will meet with this singular anomaly in no other complaint, neither in idiopathic convulsions of infants, nor in typhoid fever. I am right, therefore (he goes on to say), in attaching considerable importance to this symptom, which is of greater value than all others in making a differential diagnosis between typhoid fever with brain symptoms and cerebro-meningitis." I do not know to what extent the general opinion would now confirm the dictum of the illustrious French physician, but assuredly we shall all feel that, especially on such a question, his is an opinion which is entitled to the utmost respect. It is hardly necessary to refer to the importance of not mistaking the sighing breathing—the hydrocephalic sigh—so common in advanced cases of acute meningitis (tubercular) for the symptom now under consideration: the two, we know, can hardly be confounded.

With respect to my own experience of Cheyne-Stokes respiration, while it has comprised a considerable number of cases, it can hardly be adduced as of value, seeing that I have no notes of the cases. Perhaps, however, I may say that I have observed the symptom in acute hydrocephalus, in apoplexy, and in advanced heart disease associated with atheromatous degeneration, and that in all such instances death has soon followed its development.

From the foregoing statement it will be manifest that the morbid states with which the Cheyne-Stokes phenomenon has been found associated are various, and that it is not pathognomonic of any single condition. The practical conclusion, therefore, would seem to be that, upon encountering the symptom in any given case, we should guard ourselves against thinking too much of the medulla and too little of disease elsewhere, upon which the altered respiratory rhythm may very possibly depend.

It will be evident, however, that the question as to the ultimate causation of this peculiar rhythmical dyspnœa as yet remains untouched. The subject, indeed, is surrounded with difficulty, and probably it may be said with truth that the majority of the most competent authorities remain dissatisfied with the various theories which have been propounded. Thus we find so acute an observer and excellent authority as Broadbent expressing himself distinctly to this effect.

In considering this question, it will be apparent that there must be, in all the diseased conditions which have been shown to be associated with and to give rise to this symptom, some common feature or influence which serves as the potential factor in its production. Now Traube supposes that they have such a common feature, which is their influence in impairing the due arterialisation of the blood, and so lowering the irritability—*i.e.*, the normal responsiveness—of the respiratory centre in the medulla oblongata. In physiological conditions, as we know, this centre is called into activity by the carbonic acid in the blood. When then, in states of disease, the irritability of the centre is materially lowered, a much greater than normal accumulation of carbonic acid in the blood will be necessary to rouse it into action. Now upon this theory the long respiratory arrest gives time for the accumulation of carbonic acid in excess in the blood. Arrived at a certain maximum, this begins to stimulate the respiratory centre, slowly and imperfectly at first, afterwards in increasing degree, thus developing the respiratory movements till they culminate in dyspnœa. Arrived at this point, the free respiration rapidly oxygenates the blood, which then ceases to stimulate adequately the medulla, and again the state of apnœa results. Traube's theory has been modified and extended by Filehne, and recently Dr. Byrom Bramwell, in his work on "Diseases of the Heart," has propounded an elaborate explanation based upon a supposed condition of "irritable weakness" of the respiratory centre in the medulla. That there is in all cases of Cheyne-Stokes respiration a lowered, or, at any rate, modified irritability of the respiratory centre appears certain, the difficulty consists in accounting satisfactorily in all cases for this paresis of the centre, *given which*, Traube's explanation of the phenomena appears complete. It appears to me, however, that the question further arises, how is it that the causes considered to be capable in one way or another of lowering the irritability of the respiratory centre being of common occurrence, the Cheyne-Stokes phenomenon is not very frequently, instead of being only rarely, encountered?

With respect now to the influence of the Cheyne-Stokes symptom on the question of prognosis in any case in which it is manifested, we know that it rarely occurs in the early stages of any disease, but that, on the contrary, it usually appears within a short time before death, and that it is, therefore, an indication of the gravest import. I may confess that, for my own part I was in the habit of considering it as practically always significant of an approaching fatal termination, until my inquiries in connection with this communication showed me that recovery after the manifestation of the symptom was less rare than I had imagined. I have already incidentally referred to one of Broadbent's cases (apoplexy) in which recovery occurred, notwithstanding the Cheyne-Stokes symptom; also to Wharry's case; and now I may mention another case given by Broadbent, one of uræmia with Cheyne-Stokes respiration, which went on to a good recovery. As regards the occurrence of the phenomenon in apoplexy, indeed, Broadbent affirms that it bears no relation as a symptom either to the seat or severity of the lesion. Whether this be so or not, having regard to the well authenticated recoveries, we may take it that the symptom is not an *absolutely fatal* indication, and perhaps this is as much as can safely be said.

As regards treatment of the dyspnœa, this, of course, in the main resolves itself into treatment of the affection with which the symptom is associated. Nevertheless, cases occur in which the dyspnœa itself demands our efforts for its alleviation apart from the treatment of the primary affection. We know that, in a large proportion of instances, it is associated with coma more or less pronounced, and in such cases, of course, it calls for no special remedy. But other cases also occur, especially those in association with heart disease, in which consciousness is fully retained, and in these the symptom is often a source of much distress to the patient. Exhaustion is gradually produced by the constantly occurring dyspnœa; the patient cannot rest; sleep, if it occurs, is troubled and soon broken, the sufferer awaking in terror with a start, usually at the acme of a dyspnœal period. In a well-marked case of this nature which I recently saw with Dr. Lodge of this town the patient's distress and suffering were painful to witness. Now, according to Guttmann and others, a condition of increased arterial tension and blood pressure is always present with Cheyne-Stokes respiration. It is, therefore, found (according to the same authority) that the dyspnœa may invariably be arrested at the very commencement of each seizure—*i.e.*, each cycle—by the inhalation of nitrite of amyl, which dilates the vessels. This drug may, therefore, be tried as a palliative, but the well-known transcience of its action will probably render it of doubtful real efficacy. Possibly nitro-glycerine, which we know is similar in action to nitrite of amyl, but more permanent in its effect, might succeed better. This is merely a suggestion, for I have had no experience as yet of these drugs for the symptom under consideration. Chloral has been recommended, and I have given it with temporary relief; probably it should be combined with a stimulant.

◆

SEMINAL VESICLES. (a)

By JAMES T. CARTER, F.R.C.S.E.,

Examiner in Anatomy at the Faculty of Physicians and Surgeons, Glasgow.

My remarks are restricted principally to the seminal vesicles, with occasional reference to the other organs accessory to generation. There appears to be very little known as regards the functions of these organs, probably owing to the difficulties which are met with in obtaining any of the secretions in a separate condition. My attention was drawn to them from some observations made by John Hunter, who was strongly of opinion that the generally accepted ideas of the functions of these bodies was erroneous. With the object of confirming or otherwise, Hunter's observations, I thought an opportunity presented itself to examine and compare the seminal vesicles and their contents, as found in the entire horse and gelding, especially as no mention is made of any variation in size or nature of contents in the various treatises on the anatomy of the horse. It would also do away with any necessity for vivisection.

In the gelding I find the seminal vesicles to consist of two pyriform sacs situated on the upper surface of the bladder, and having the vasa deferentia and vesicula seminalis tertia or sinus pocularis between them. The duct of each sac joins the vas deferens of its own side, at an acute angle about ⅜'' from the urethra. Each sac extends forwards between the bladder and rectum for a variable extent according to their distension, the fundus and upper surface for 1½ to 2 in. being covered with peritoneum. The average capacity when well distended in a fair sized animal is about 1¾ oz. Each sac consists of an outer complete fibrous coat, beneath which is found a double layer of non-striped muscular tissue, the deeper layer having its fibres running in a longitudinal direction, the more superficial layer being transverse. The cavity of the vesicle is lined with a mucous coat, covered with columnar epithelium. This coat at the neck of the vesicle is quite smooth, but as you pass upwards transverse rugæ begin to make their appearance, which increase in size towards the fundus. Near the fundus of the sac the duplications of the mucous membrane present the appearance of scales, the transverse arrangement of the rugæ disappearing, and from the fundus projecting into the cavity of the vesicle, there is a large mass of long scaly folds. At this point the muscular coat is greatly increased in thickness. The mucous membrane is perforated by a great number of wide-mouthed branching tubular glands, lined with nucleated columnar cells, the nuclei being situated in that part of the cell most distant from the mucous surface. The rugæ at the lower portion of the sac disappear on distension, but the folds at the upper end are permanent, and are no doubt to serve as an increased secreting surface. The two vesicles are connected at their anterior half by the fold of peritoneum which covers them, and beneath this is a thickish transverse band of muscle fibre, which bridges across from one vesicle to the other and also covers their upper surfaces. This band of muscle forms the compressor vesiculæ et ductus seminis, and covers in the two vasa deferentia, behind it is lost on the surface of the prostate. The fluid contained in the vesicles of the gelding is thick and viscid, and has a milky appearance. It has a neutral reaction, and coagulates into a soft jelly shortly after death. Under the microscope it is seen to contain a large number of coarsely granular, roundish, nucleated cells, with granular *débris*. On keeping a small quantity in a test tube for a short time, the soft jelly-like mass becomes slightly more fluid, and the cells and *débris* fall to the bottom, leaving a clear-looking semi-fluid substance, with a slight brown colour. After comparing the vesicles of the horse and gelding, there appears to be no difference as regards size, in fact atrophy has not taken place in the latter animal. The capacity is the same, and I have several times measured as much as ¾ oz. of fluid taken from a single sac in the castrated animal. The fluid found in the vesicles of the stallion, however, differs from that found in the gelding in containing a few spermatozoa, but not in the enormous numbers as seen in the semen after ejaculation. The ampulla-like termination of the vas deferens as seen in the stallion, and which extends for about 5½ in. along that tube, has disappeared in the gelding, the calibre of the deferential canal and the great thickness of its walls having also become greatly diminished.

(a) Read before the Glasgow Medico-Chirurgical Society.

Function.—The general accepted opinion of the function of these bodies is that they form a reservoir for semen, and thus in a manner resemble the gall bladder which acts as a reservoir for the bile. The remarks in Quain's last edition of Anatomy may be taken as an index of this general opinion. On page 696 it says: "The seminal vesicles serve as receptacles or reservoirs for the semen, as is proved by a microscopic examination of their contents; but, besides this, it is probable that they secrete a peculiar fluid which is incorporated with the semen."

Hunter was distinctly of the opinion that the seminal vesicles are not reservoirs for semen. He arrived at this conclusion from a number of observations on castrated guinea pigs. He also examined the bodies in several subjects which had the testicle of one side removed some time before death. In each case the vesicle of the extirpated side was as full of fluid as that on the other side. These observations of Hunter have been enlarged upon in a very able article by Mr. S. R. Pittard, in the "Cyclopædia of Anatomy and Physiology" for February 1852. The basis upon which the function of the seminal vesicles, principally rests, as a reservoir for semen, is that the amount of fluid ejaculated is far greater than is capable of being contained in the ampulla-like termination of the vas deferens, even when that is present; and also on the knowledge that spermatozoa have been seen in the fluid contained in these sac-like bodies.

Taking together all the facts known in connection with the seminal vesicles, I think however, it is more probable not that they act simply as receptacles for semen as secreted by the testicles, but secrete themselves, and store up a fluid, a liquor seminis, which acts as a medium and diluent to the fluid formed by the testicles; the latter fluid being in a concentrated form and only secreted in quantity at stated periods as in the rut of some animals, or kept in reserve in the enlarged termination of the vas deferens as is found in man, and other animals, and especially in the elephant.

There is no doubt that spermatozoa the essential ingredient of semen are found in the seminal vesicles of both man and other animals, but after examining a number of specimens taken from the horse, I found that they were present in comparatively few numbers, to the enormous quantity found in the semen after ejaculation, as has been remarked by other observers, and it is easy to account for those found when we consider the activity of these small vitalised bodies together with the easy means of passing into a sac containing a medium congenial to them. If these structures simply act as reservoirs for semen we would expect atrophy to take place in a castrated animal, similar to that found in the vas deferens, on the contrary, however, the vesicles not only present no diminution in size in the gelding but are found more or less distended with a fluid secreted by themselves, which fact, alone would confirm Hunter's statement that they act as secreting organs. In some of the rodents also the seminal vesicles open by a separate orifice in the urethral canal, and do not therefore form a kind of diverticulum of the vas deferens. In these animals it would be necessary for the semen to enter the urethra before passing into the vesicles, which would be an improbable course. That the secretion of the seminal vesicles, granting that they have a secreting function, together with those of the prostate and Cowper's glands have more or less a similar purpose to perform is rendered probable by an examination of the comparative anatomy of these organs, and also from the fact that they make their first appearance in the vertebrate animals together with a complete urethral canal. This may account for the necessity of an increased bulk of seminal fluid as it is generally believed that both the secretions of the prostate and Cowper's glands perform the office of a diluent to the semen, and together with these we may add that of the seminal vesicles. The secretions of all three organs are more or less viscid. I have not yet been able to examine carefuly the fluid formed by Cowper's glands, but the prostrate secretion in the horse is a thickish semi-fluid clear viscid substance with a brownish colour, it hardens very rapidly after death, so quick that it is difficult to obtain specimens soft enough to allow of manipulation under the microscope, it was seen to contain cells of a similar appearance to the vesiculæ secretion. They were oval and columnar in shape, nucleated and finely granular, but few in number.

The accessory organs are absent in birds, reptiles, and fishes, but appear in the monotremata and marsupials with a closed urethra. In a number of animals one or other of the glands may be absent, for we find in the monotremata just mentioned the seminal vesicles are wanting, but they appear to be compensated for by the relatively large size of Cowper's glands. In the rodents the seminal vesicles are generally large, the gray squirrel is, however, an exception, the vesicles in this animal being diminutive, but both the prostate and Cowper's glands are large. In the carnivora the seminal vesicles are absent. In the bull the seminal vesicles have the appearance of two lobulated glandular masses, the prostate is small and Cowper's gland's are absent. Not only may one or other of these organs be absent, but even when present there is a diversity as regards their form, for in the beaver the prostate consists of short pyriform sacs, and in the rat of convoluted tubes.

When we take into consideration all the facts we know relative to the seminal vesicles it becomes exceedingly probable that their secretion performs a dual function, viz., acting both as a diluent to the concentrated testicular fluid, and no doubt as a protective lubricant to the urethral canal.

During coition I think it probable a strong vermicular action is set up along the vas deferens which drives the spermatozoa towards the common ejaculatory duct, at the same time powerful contractions of the muscular wall of the seminal vesicles force out the fluid contained in them, and the result is a mixture of the two fluids which is violently ejected into the urethra. This forcing out of the vesicular fluid and spermatozoa towards the urethra is facilitated by the obliquity with which the seminal vesicle joins the vas deferens to form the common ejaculatory duct.

◆

We are asked by the authorities of the University of London to state that as the celebration of Her Majesty's Jubilee will fall in the week in which the usual halfyearly Examination for Matriculation commences, this examination will take place a week earlier, viz., on the 13th instead of the 20th of June.

Clinical Records.

CASES IN COUNTRY PRACTICE.

Under the cars of Jas. Martin, F.R.C.S.

Case 1.—*Removal of Externa Ear for Cancer.*

Six months ago I was called to an old man, æt. 81, and a hard drinker. His right ear was a mass of epitheliomatous cancer about the size of an orange, and bloated extensively. He suffered greatly from the inconvenience it caused and severe lancinating pains, there was a patch adjoining the skull about the size of a sixpence, apparently sound and no more, the entire structure of the external ear was involved. The man was so worn out and feeble that I was afraid that if I removed the mass by excision, the loss of blood, even if trifling, might prove fatal, and he having himself an inseparable dread of the knife, I determined to remove it by elastic ligature. I, therefore, passed a needle armed with a double ligature of india-rubber, through the sound part, and tied it above and below. I then applied water dressings with some tr. of opium over the tumour, desiring that it should be kept constantly wet. The following day I found the old man rather flushed and excited. He had taken a very small amount of stimulants, his pulse was extremely feeble, 100; and he had very little sleep, but he did not complain of pain. I ordered him two glasses of wine daily. gave him a draught of 15 grs. chloral hydrate, 15 grs. bromidi potass, 15 drs. liq. morphine, i dr. of spirits sulphuric ether, and applied an antiseptic lotion of glycerine and boracic acid 2 oz., dissolved in pint of water. He slept well, had no further unpleasant symptoms. I tightened the ligatures on the third day, it having then cut nearly half-way through, and on the eighth day a slight nip of a scissors removed, leaving a small healthy granulating patch about the size of sixpence. It healed perfectly, and no further symptom has appeared since. He is now enjoying as good health as he has had for years.

Case 2.—*Large number of Gall Stones passed without pain or inconvenience.*

I was called to see a woman, æt. about 65, of a pallid fair skinned face, with a certain air of refinement, she has been suffering for some time from ordinary dyspeptic symptoms, and has evidently a very weak heart, the impulse being very much below what would be normal. While talking to her about her symptoms, she said that she had passed some hard bodies, which she had washed and put by. When I expressed my desire, she produced four gall stones of the usual facetted appearance, and after some conversation she said that she had passed a large number besides, but then she only washed them, and left them outside the house in a tin vessel. On asking to see them, a tin vessel, which would hold about a quart, was brought in, containing about two hundred, all oval, of the size and colour of olives. I could not reckon them accurately, as those at the bottom, lying in water, were macerated and softened, and had lost their distinct outline and shape. They had all passed away without giving pain or trouble, but one of her objects in consulting me was to get some treatment likely to prevent a new formation. In connection with this, I may mention that a near relative of mine having died of the effects produced by the impaction of a mass in the common duct, I got my friend, the late Dr. Cavet, of Waterford, to make a post-mortem examination, when he found that the offending body was a mass the size of a large man's thumb, formed by the agglutination of a number of pisiform bodies. This was looked on then as being beyond recovery. How different would it be now. Dr. Cavet also informed me that the hepatic ducts were filled with hundreds of those pisiform bodies of a light pale yellow colour. Many such cases are on record, but I do not remember any in which such a number and of such size were passed during life with so little trouble as in this old woman. The old lady is now doing well, and has passed a few more since I saw her.

◆

METROPOLITAN FREE HOSPITAL.

Case of Chancre of the Lip.

Under the care of Dr. Charles R. Drysdale.

Cases of hard chancre of the lip are sufficiently uncommon to make each one worth recording. On Tuesday, March 1, 1887, a respectable young woman, æt. 28, a milliner by trade, presented herself among Dr. C. R. Drysdale's out-patients at the hospital, for what she styled "a cold in the lip," and which she had noticed for about fourteen days. There was a swelling of the lower lip in the middle line, which felt wooden in its hardness when taken between the finger and thumb. An abrasion of about the extent of a sixpence was seen on the surface of this swelling, at the punctures of the skin and mucous membrane. The glands beneath the jaw on both sides of the middle lines were enlarged and hard. No eruption existed on the face or body. Patient was engaged to be married and had been kissed by her intended husband whilst he was suffering from a sore mouth.

◆

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

Friday, March 11th, 1887.

Dr. Broadbent, President, in the Chair.

Dr. de Havilland Hall communicated a case of

PNEUMOTHORAX WHICH HE HAD HAD UNDER OBSERVATION, WITH NOTES OF FOUR OTHER CASES.

Case I.—F. R. P., æt. 24, a clerk, was sent to Dr. de Havilland Hall by Dr. W. D. Penny on June 27th, 1885. The account given by Dr. Penny was that on May 8th, the patient complained of sharp pain in the left side of the chest. In the mid-axillary line, low down, there was pleural friction with slight dulness on percussion and tubular breathing. The dulness only covered a very small area, and the rest of the chest was quite normal pulse, 110; temperature 100·4° F. The patient was sent home to bed, and next day there was hyper-resonance all over the chest and extending half-an-inch to the right of the sternum. Breathing replaced by amphoric roaring and loud tinkling, except that at the angle of the scapula the respiratory murmur was faintly audible. Heart sounds muffled, apex bent half an inch inside right-nipple pulse, 140; temperature, 99° F. The patient stated that while getting into bed he suddenly felt faint, and had a peculiar sensation about the heart. In the course of a month the symptoms slowly subsided, the heart returned to its natural position and the breath sounds returned. A fortnight later there was a return of pain and shortness of breath. When examined by Dr. Hall the patient had just come from business. There was only slight complaint of pain and there was not much dyspnœa, pulse 120; heart sounds clear. Impulse in epigastrium. The left side of the chest hardly moved at all, there was general hyper-resonance and obliteration of the cardiac dulness. No breathing sounds were audible over the left side. The bell sound could not be elicited, The right lung was normal. The urine contained a trace of albumen. On September 30th, the patient was again examined and both lungs were found perfectly free from disease.—*Case II* (Notes supplied by Mr. B. Rix of Tunbridge Wells). J. W., æt. 39, mason's labourer, previous health good, and in constant work for past 11 years. While sweeping, seized with sudden pains just above the left nipple and came over faint. Continued at work for five days, but owing to increasing dyspnœa and pain had to take to his bed on the fifth day. On examination, there were the physical signs of pneumothorax on the left side. He was under observation for seven weeks during which time the heart gradually resumed its normal situation, the hyper-resonance disappeared and normal breathing returned.—*Case III.* Recorded by Dr. Delgrange (see London *Medical Record*, 1881, p. 196) a healthy youth, æt. 19, while exhibiting the powers of his chest suddenly felt severe pain in the left side, his face became blanched and he experienced great oppression. During an effort to vomit he was seized with a sense of something tearing in his side, followed by syncope, there were unmistakable signs of pneumothorax. The patient recovered after about eight days.—*Case IV* (Recorded by Biermer, *Würzburgher Med. Zeitschrift*, Bd. I, p. 385). K. D., a law student, æt. 19, while dancing was seized with a peculiar sensation in the region of the heart, accompanied with giddiness, oppression and sweating; when examined four days later, there were the physical signs of pneumothorax on the left side accompanied by a moderate amount of liquid effusion. In seven weeks all objective signs of the pleural affection had disappeared.—*Case V* (Recorded by Ricker, *Wien. Med. Wochensch.*, March 28th, 1860). A badly developed young man of 18 years of age, was seized, while coughing, with a stabbing pain in the left side. A week later, he complained of considerable shortness of breath and the physical signs were those of a pneumothorax. The distress increased so much that he was punctured, and the operation was followed by an alleviation of all his symptoms. Two months later, he presented a more healthy aspect than before his illness. After remarking on the comparative rarity of cases of pneumothorax occurring among the apparently healthy, Dr. Hall drew attention to the cases collected by Dr Samuel West, in a paper read before the Society in 1883, and to the cases reported to the Medical Society in March, 1886, by Dr. Whipham. Dr. Hall considered that the explanation of great preponderance of males over females in the subjects of this affection is to be found in the greater muscular exertion of males compared with females, and that whatever might be the predisposing cause, the immediate cause of the pneumothorax is some strain. He had no doubt that in a majority of cases the rapid breaking down of a small tuberculous mass before a secondary pleurisy had had time to set up adhesions, was by far the most frequent cause of pneumothorax. The paper concluded with some remarks on the diagnosis and treatment of pneumothorax.

Dr. **Burney Yeo** said that during ten years experience at Brompton he had never met with such a case as those described by Dr. Hall. He would suggest that sufficient stress had not been put on dry pleurisy as a cause of the condition. This form of pleurisy might easily escape notice, or be discovered only by accident.

Dr. **Stephen Mackenzie** quoted the case of a young gentleman who was seized with symptoms of pneumothorax while apparently in perfectly good health. He had noticed "stitch" in the side on several occasions.

Dr. **Samuel West** said he had had one or two cases which bore out the statement which had been made. In a man of fifty the symptoms of pneumothorax were so obscure that he was several days in the hospital before it was remarked. He died soon after, and the disease of the lung was limited to a nodule. He thought most cases were tubercular. He had recently been making some experiments on the pressures at which healthy lungs would burst, and without giving any precise details, the pressure seemed to be much greater than that which would be caused by respiratory movements. He mentioned that he had never met with a case of pneumothorax after accident or injury to the ribs.

Mr. **Sidney Coupland** said he agreed with Dr. Hall that pneumothorax was often associated with small localised phthisical changes. He would add two cases of this lesion to the list; in neither of them was there any phthisis nor history of phthisis.

Dr. **Turner** said he had had a case of traumatic pneumothorax recently in his practice, and on inquiring as to its frequency he was told it was very rare.

Mr. **Rivington** said he would say that in the course of seventeen years' experience, during which he had seen a large number of fractured ribs, he had only seen one or two cases of pneumothorax resulting therefrom.

Mr. **Howard Marsh** alluded to the case of a lad who was admitted into St. Thomas' Hospital, having been run over. His breathing was greatly distressed, and he died soon after. At the post-mortem the lung was found to have been torn bodily away from the bronchus.

Mr. **Bernard Pitts** said he had seen several cases of traumatic pneumothorax. In one case aspiration had been performed twice with benefit to the patient, who, however, died, and was found to have a rupture of the lung.

Dr. **Broadbent** said he had seen three cases some years ago.

Dr. **Hall**, in reply, said that he could not agree with Dr. Yeo that pleurisy was a common cause of pneumothorax, and if present was probably due to phthisis like the other lesion.

Mr. **Frederic S. Eve** on a case of

INTRA-PERITONEAL EXCISION OF THE RECTUM WITH RECOVERY.

The patient, a woman, æt. 34, had suffered with symptoms of cancer of rectum for nine months. The growth encircled the rectum, and it was thought that the finger could be passed beneath its upper margin. The usual operation of excision was undertaken, but as the upper limit of the growth could not otherwise be reached, the peritoneal reflection encircling the bowel was divided, and the diseased portion removed with the écraseur. The bowel excised, measured nearly six inches in length. The upper end was readily brought down to anal margin. Patient is now, five months after operation, in good health. Good recovery, without symptoms of peritonitis. Remarks in recent researches on the experimental production of peritonitis tending to show that this operation should not theoretically be exceptionally dangerous, and that the limits of cases deemed fit for operation might be determined.

Mr. **Harrison Cripps** said he had performed a great many cases of excision of the rectum during the last few years, in about 1 out of 5 having had to remove a portion of peritoneum. No death had resulted. He thought the difficulties of the case had been greatly exaggerated.

Mr. **Golding Bird** asked how far the patient could retain her motions?

Mr. **Eve**, in reply, said he was surprised to hear from Mr. Cripps that the peritoneum was opened and part of it removed in so large a proportion of cases. In his own case the peritoneum had been cut through all round, so as to allow of complete examination of the gut above the site of the growth. He was unable to say what the condition was at present as regarded retention of fæces.

A CASE OF SCOLIOSIS.

Mr. **Keetley** having received from Mr. Bernard Roth a paper on the results of the gymnastic treatment of scoliosis, asked that gentleman for permission to see the treatment. Mr. Roth consented, on condition that Mr. Keetley should send him a case (of the hospital class) for treatment. This condition being fulfilled, Mr. Roth (with Mr. Keetley's consent) exhibited the patient at the Clinical Society twice, once before and once after, a course of gymnastic treatment. Mr. Roth's views of this case are stated (with illustrations) in the Clinical Society's Transactions. Mr. Keetley, while acknowledging that the patient's spirits and muscular strength were improved by the gymnastics, states that she had lost in height, and that the scoliotic curves had undoubtedly increased during the treatment.

Mr. **Bernard Roth** said the patient had been sent to him by Mr. Keetley with a request to do what he could for her, and no intimation was given of an intention to read a paper until last Saturday; further, he had applied in vain to know what line of criticism Mr. Keetley intended to follow. He defended his history of the cases reported in the Transactions, and protested against Mr. Keetley's paper being published by the Society unless his answer was appended. The patient in question had suffered from lateral curvature for ten years, and had been under various treatments. In spite of plaster jacket, &c., she had become frightfully deformed, and this had gradually got worse. He had told Mr. Keetley that he would do his best, and would make her independent of spinal supports in three months, though the osseous deformity would of course remain. He showed photographs and tracings of the ribs. The patient was shown at the Society in Nov., 1885, and again after the three months' treatment in March, 1886, and Mr. Keetley then made no objection. Both patients were present, and had been examined by members. If his reply could not be appended, he would urge the appointment of a committee to report upon the cases, as well as on the case which he had shown in April, 1883.

Dr. **Broadbent** thought that the best course would be to appoint a committee.

Mr. **Heath** said that Mr. Keetley had applied to the Council because he felt aggrieved that a case of his had been used without his permission in support of views which he was not prepared to endorse. He had received permission to read a paper on scoliosis, but it had not been anticipated that it would be of such a controversial nature. He agreed that the appointment of a committee was desirable.

This was put to the Society and agreed to.

LIVING SPECIMENS.

Mr. Robinson and Mr. Parker: Congenital Deformity of Hands and Feet in three generations.

Mr. Bernard Roth: Two Cases of Scoliosis.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

Meeting held Wednesday, March 2nd.

The President, Professor **Grainger Stewart**, M.D., in the Chair.

PATHOLOGICAL AND OTHER EXHIBITS.

Dr. Carmichael showed the brain from a case of tubercular meningitis; Mr. **Miller**, the lower extremity removed on account of a peculiar form of gangrene of the foot and leg; and Dr. **Bruce**, a new form of radial microtome, devised by himself and Mr. Fraser, optician, which was less costly than the instruments already in use, while equally efficient.

DISCUSSION ON CEREBRAL ABSCESS.

The discussion on the Diagnosis and Operative Treatment of Cerebral Abscess due to Ear Disease was opened with papers by Dr. M'Bride and Mr. A. G. Miller.

Dr. **M'Bride** explained that cerebral complication was more common after chronic than after acute ear disease. Such complication might take one of three forms, viz.: abscess, meningitis, thrombosis. In some instances, two or more of these might be combined. His experience led him to the conclusion that, in a large proportion of cases, it was impossible, from the symptoms alone, to say which form was present, in a given instance. Doubtless, some symptoms suggested a presumption in favour of one or other, as for example, the exact seat of tenderness, the appearance of bogginess over the mastoid region, the condition of the pulse and temperature and, as especially indicative of sinus phlebitis, the occurrence of pain and swelling over the line of the internal jugular vein. Did they obtain more exact information from an examination of the ear? The data at their disposal consisted largely of statistical tables drawn up by different observers. Toynbee had spoken of abscess following on disease of the external meatus. This was questionable. Rosa stated that over 50 per cent. of secondary cerebral affection took the form of cerebral abscess. Dr. M'Bride feared that in this number must have been included some cases of purulent meningitis. He had compiled a table himself, in which only such cases were included as had been examined by a competent aurist, and the parts submitted to careful dissection after death. The table was as follows:—

Form of Cerebral Affection.

Part of Ear affected.	Cerebral Abscess.	Purulent Meningitis	Cerebellar Abscess.	Thrombosis.
Tympanum and Mastoid region ...	12	8	3	8
Tympanum only ...	3	1	0	1
Middle and Internal Ear	0	3	4	1
	15	12	7	10

The figures spoke for themselves. When the internal ear was affected, it would be observed that cerebellar abscess was more frequent than cerebral. Hence the tuning fork test might come to be of value. Granting the probable presence of an intra-cranial abscess, they might judge it more likely cerebellar if the sound conduction were lost in the affected ear, while if the sound conduction were greater, it was probably cerebral. He questioned Mr. Hulke's view that cerebral abscess was commoner in the young and cerebellar in the adult. His experience pointed towards an opposite conclusion. If an abscess had been diagnosed, what line of treatment must they adopt? The results of recorded operations and the development of cranial surgery pointed to operative interference. The safest method appeared to him as follows:—A curved incision should be made over the auricle and that structure dissected out. The cranium should then be opened about a quarter-inch above, and just in front of, the osseous meatus. In the large majority of cases, this site would be found nearest to the origin of the evil. It had the further advantage that it was far removed from the course of the middle meningeal artery. Dr. M'Bride concluded by criticising the diagnosis and operative treatment in the case recently reported by Professor Greenfield. No sufficient data has been given for the view adopted.

Mr. A. G. **Miller** read the clinical record of two cases, in which, after consultation with Drs. M'Bride and Wyllie, he had operated in the way just suggested. In both instances there was temporary relief, but the patients sank under septicæmia. Mr. Miller spoke further on the alternation of head symptoms and otorrhœa, and advocated a more scientific treatment of chronic ear discharge, with a view to the prevention of the more serious consequences.

Professor **Annandale** approved of the lines indicated by Dr. M'Bride for operative interference. There was no question that the larger proportion of such cerebral abscesses were directly connected with, or in close proximity to, the suppurating ear cavity. The site suggested had the further advantage that the operation was not likely to be provocative of serious hæmorrhage. There was certainly need for the rigid institution of preventive measures. If free drainage of the otorrhœa were adopted, they would have fewer cases of cerebral complication.

Professor **Greenfield** explained that the chief difficulty in his case lay in the fact that there was no clear history of antecedent ear disease. He had seen several instances where the cerebral abscess was further forward, even in the frontal lobe. Perhaps he had laid too much stress on a certain parallelism which he felt to exist between the recent case and others he had seen. The result, however, justified his conclusions.

Dr. **Bramwell** said that, in his experience, cerebral abscess following on ear disease, was rare. During long service as pathologist in Newcastle and Edinburgh, he had only met with two cases. They must sharply differentiate between an encapsuled and a non-encapsuled abscess. He did not think the encapsuled abscess was in any way to be separated clinically from a cerebral tumour. Too much stress had been laid on optic neuritis as an infallible indication of operation. While he admitted that it was a weighty piece of evidence, they must bear in mind that the occurrence of optic neuritus did not necessarily mean a fatal issue. Cases were on record, where optic neuritis had been completely recovered from. As abscess, consequent on ear disease, was so frequently situated in the temporo-sphenoidal lobe, they should, especially when the condition was left-sided, seek for the existence of *word-deafness.*

Mr. **Caird**, who trephined in Professor Greenfield's case, warmly defended the site chosen. He was led to understand that the pressure symptoms pointed to the presence of an abscess further forward than usual, and he operated where he did, just as he would open a psoas abscess which was pointing in the abdomen, even though the source of the evil was distinctly spinal.

Professor **Chiene** agreed with Mr. Caird's view as to the wisdom of the selection. The symptoms of pressure on the third and fifth nerves, and the shape of the middle cranial fossa, in his opinion, thoroughly justified the course.

Dr. **Hughes Bennett** (London), could not speak from much experience of cerebral abscess. His belief was that, following on ear diseases, it was rare. The rapid advances which cerebral physiology and surgery had made within the last few years were the best defence of operative interference, He had taken part in a large numbers of operations for epilepsy and in only one instance, with fatal issue. It had been found that the mere trephining was frequently curative, even when no definite cause for the condition was forthcoming. In such circumstances, they must remove a portion of dura mater with the bone.

◆

THE BRITISH GYNÆCOLOGICAL SOCIETY.

Meeting held March 9th, 1887.

Dr. G. **Bantock**, President, in the Chair.

Dr. Alfred Meadows showed a specimen of tumour which he had recently removed from a patient, and though the two Fallopian tubes were evident, no trace of an opening corresponding to cavity of uterus could be found. The tumour was removed by the extra-peritoneal method. In the subsequent discussion the question arose as to the length of time the clamp should be left on pedicle after operation. Mr. Lawson Tait was said to sometimes remove it at the end of four or five days, but Dr. Bantock thought ten days was about the best time provided the stump dried up nicely. In choice between extra and intra-peritoneal operations Mr. Reeves advocated the mixed, but Dr. Bantock was decidedly in favour of extra-peritoneal.

Mr. **Spanton** showed some specula made of porcelain lined with platinum. He had used them and found them very effectual and cleanly.

A discussion followed on the requisite length of a speculum, great diversity of opinion evidently existing.

Dr. **Purcell** read a paper on

VAGINAL HYSTERECTOMY FOR MALIGNANT DISEASE,

instancing three cases, all of which recovered. In the first case a woman, æt. 40, mother of five children, youngest four years old. Her illness dated back eight months, and about three months ago she had a small mass moved from the os uteri. After being anæsthetised a cancerous growth, about the size of a cricket ball, was removed by galvanic écraseur and plantinum wire on a line with the internal os, and without loss of blood. On examination it was found that all the disease was not removed, so it was decided to remove the whole of the uterus. The case was published in full in the *Lancet* of Jan. 31st, 1885. Catheter was retained until sixth day. She was allowed up on the twenty-fifth day after operation, and she left the hospital on the forty-second day after operation. She presented herself several times after at the hospital, and appeared to be doing well, but ten and a-half months after operation a letter was received saying she had died, but no information could be obtained as to cause of death. In the second case, a thin delicate woman, æt. 42, mother of six children, there had been two floodings. Epitheliomatous disease was found in posterior lip and body of os uteri, also vagina. The uterus and appendages were removed, and she left hospital thirty-two days after operation. Seventeen months after operation she was quite well. In the third case, a married woman, æt. 29, mother of five children, youngest five years. Disease noticed five months ago. On examination a large growth was found to occupy the vagina, growing from the anterior lip of the os uteri, the disease extended to wall of vagina posteriorly, and to the right. The tumour and part of uterus were cut off by écraseur and Emmet's scissors at level of internal os, but disease was found to extend higher, so total extirpation was performed, the two ovaries being left *in situ*. Allowed up on sixteenth day after operation, and walked about ward by twenty-fourth day. Dr. Purcell doubted the advisability of extirpating if superficial primary cancer of the vagina existed to any extent. Cancer of the cervical mucous membrane and body of uterus always necessitates total extirpation of the organ.

Mr. **Reeves** thought Dr. Purcell hardly up to date in rate of mortality, which was now considered less than he stated, *i.e.*, about 28 per cent. His great difficulty was to arrive at a fully satisfactory diagnosis of the extent of the disease before the actual operation commenced.

Dr. **Bedford Fenwick** urged strongly the attempt at diagnosis per rectum.

Dr. **Grigg** also said abroad he had seen chloroform given to its extreme limit with safety, and then the hand per rectum or vaginam used to thoroughly explore surrounding tissues.

Dr. **Edis** laid special stress on the importance of early diagnosis.

Mr. **Bland Sutton** said the ureters were usually a source of trouble in the vaginal operation.

In reply, Dr. **Purcell** thought the examination by hand in rectum a difficult and somewhat dangerous performance. In two out of the three cases extirpation was not decided on until a minor operation had been performed and demonstrated the necessity. The ureters could be felt in the broad ligaments, and so with care be avoided.

◆

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

Monthly Meeting, February.

Isaac Mossop, Esq., President, in the Chair.

Mr. **Mercer** introduced the following

CASE OF EMPYEMA.

William B., æt. 6, on August 3rd had an attack of acute pleurisy. This was followed by effusion into the right chest, occupying two-thirds of the cavity. The usual treatment was followed for a fortnight. At this time the case had evidently become one of empyema, marked by bulging of intercostal spaces, great loss of flesh and diarrhœa. On August 23rd under an anæsthetic (chloroform) I explored the chest with a syringe, withdrawing pus. I then made an incision with a scalpel into the 8th interspace, near the angle of scapula, one inch long, I inserted a red rubber drainage tube, held from slipping into the cavity with a thread. I covered the whole with salicylic silk and bandage. The operation was done *à la* Lister. In the course of fourteen days or more the tube came out, and the wound healed. The boy now rapidly gained flesh and strength, the right lung became resonant, and respiration re-established. From beginning of the illness to its termination would be about six weeks.

Dr. **Goyder** congratulated Mr. Mercer on the rapid cure of his case, the cases were generally more tedious, though children did better in this respect than adults. He mentioned a case which had been under his care in this Infirmary which had been operated upon in Leeds. Pus escaped from the opening for about four weeks, but gradually diminished, the wound healed, and the lung gradually restored to its normal size, no precautions but cleanliness and the usual dressings were employed. In ordinary serous effusion he rarely aspirated till blistering and diuretics were used, and these generally succeded in removing the effusion.

Dr. **Major** said the common experience was that these serous effusions went on to the formation of pus, why, it was difficult to say. He could scarcely say antiseptic precautions were used in this case, nor were they needful, since cases generally did well without them. The advance of surgery had shown the necessity of the early evacuation of pus, and acting on this many lives had been saved in recent years that would otherwise have been sacrificed.

Dr. **Bell** remarked that scarcely any disease so illustrated the advance of surgery as the modern treatment of empyema. Dr. Addison said in his day that every case in which the chest had been opened in empyema died. This opinion influenced practice no doubt. Now, the rule was to evacuate pus as a foreign element wherever it existed, whether in the brain, chest, or elsewhere. He advocated two openings, one above, the other below, to facilitate the discharge. Antiseptic precautions were necessary to prevent the pus becoming fœtid.

Mr. **Miall** agreed with Dr. Major that antiseptic treatment in these cases was useless, and might do harm by withdrawing attention from the necessity of making a free opening, and thereby securing perfect drainage, it had even been advocated to excise a portion of the rib to make drainage more effectual.

Mr. **Mercer**, in reply, said he followed the advice of authorities in using antiseptics to prevent putrefaction of the pus.

Dr. **Denby** then read a case of

DIPHTHERITIC CROUP.

A. B., æt. 4, began with symptoms of "cold" on Thursday, Sept. 30th. First seen on Monday, Oct. 4th. *Symptoms:*—Voice whispering and thick, as of some throat obstruction, foul odour of breath, nostrils tender and moist from discharges, slight cough of "brassy" character, temp. 101-102, pulse over 120, fauces, &c., thoroughly covered with dirty white membrane. *Cause:*—Only cause that could be assigned was that early in preceding week ashpits in back street had been emptied, and child probably playing about at the time. Prescribed mist. pot. chlor., acid hydrochloride, &c., and ordered throat to be syringed every three hours with gargle of mg. sulphis. In the evening worse, symptoms of diphtheritic laryngitis well marked. Emetic of sulph. of zinc. caused vomiting, but no membrane noticed. Patient being an only child, and other circumstances made the case one of painful interest. Instruments necessary for tracheotomy were got ready, and I slept in the house during night. Symptoms continued the same till following morning, when I was sent for about nine as she was thought to be dying. Mr. Meade, sen., saw her with me immediately. *Result of Consultation.*—As strength of child was fairly good, complexion of good colour, no urgent difficulty of breathing, no decided symptoms of pulmonary congestion, and especially considering diphtheritic character of laryngitis, it would be safer to watch carefully a while longer, and reserve any operation until more urgent symptoms developed. An emetic of sulph. of copper with same result as before. I saw her several times during day. She was watched constantly, and plied persistently with milk food. Nutrient enemata had to be abandoned. Mr. Meade saw her at 11.30 a.m. and at 9 p.m. Symptoms slightly worse, but we decided still to postpone operation. I remained in the house through the night. At 4 a.m. on Wednesday all symptoms worse, and got ready for tracheotomy at any moment. Gave another emetic of sulphate of copper with unsatisfactory result. Saw her every two hours. At 3.15 p.m. sleeping more quietly, breathing more softly, colour good, and pulse better. Had vomited about 2 p.m. a thick substance like "boiled white of egg." I charged them to let her have her sleep out. At 5.45 I found her awake with slight but decided improvement of all symptoms. I enjoined still unremitting watchfulness. However, from this time there was steady amelioration of symptoms. Syringing continued, but throat not clean until about the 14th. Cough did not lose "brassy" character, and voice did not resume its usual tone till about two weeks from commencement. Scarcely any gland enlargement at any time. No albuminuria that I remember. No sequela except nervousness. *Treatment* consisted not in any specific medicine, but in syringing regularly and thoroughly with sol. of mg. sulphis, in keeping up strength by plying her persistently with milk, &c., in constantly watching her and making her comfortable in every way, giving an enema when necessary, keeping air of room soft and warm with steam, keeping her quiet and favouring sleep so as to diminish laryngeal irritation, and result was happily very satisfactory.

A short discussion followed the reading of this case in which the President, Drs. Goyder, Johnstone and Bell took part. In reply to questions by the two latter gentleman,

Dr. **Denby** said he had not entered into the pathology of the affection. He preferred syringing to the spray as less liable to irritate the larynx. Before Mr. Gilchrist Burnie's paper he had used dilute sulphurous acid, he now preferred magnesium sulphide as less irritating.

Dr. **Herbert Major** then read a paper on

RESPIRATION OF ASCENDING AND DESCENDING RHYTHM (CHEYNE-STOKES).

which will be found at page 241.

Following the reading of this interesting paper the President, Dr. Goyder, and Dr. Denby, cited cases which exhibited this peculiarity of respiration, and remarked on the interesting *resume* which Dr. Major had given of the causes and phenomena observed by various authors.

Mr. **Miall** remarked that there was a description of similar respiration in Hippocrates, it occurred in a case of fever of which the man died, the language used was, much the same as that employed by Cheyne to describe, the affection.

Dr. **Major** thanked the members for the manner in which his remarks had been received. The various causes of this respiration would be better understood if greater opportunities for post-mortems could be obtained in cases in which it occurred. Though there might not be any heart affection in some of the cases, yet whatever the disease it ultimately so affected the respiratory centre as to produce these phenomena. He said he was aware that Hippocrates had mentioned a case of this kind.

◆

Vital Statistics.—The deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 21·3 per 1,000 of their population, and were—Birkenhead 17, Birmingham 22, Blackburn 28, Bolton 11, Bradford 22, Brighton 14, Bristol 19, Cardiff 25, Derby 20, Dublin 28, Edinburgh 22, Glasgow 25, Halifax 19, Huddersfield 26, Hull 21, Leeds 21, Leicester 19, Liverpool 23, London 20, Manchester 31, Newcastle-on-Tyne 24, Norwich 21, Nottingham 17, Oldham 24, Plymouth 24, Portsmouth 21, Preston 24, Salford 22, Sheffield 19, Sunderland 15, Wolverhampton 26. The highest annual death-rates in these towns last week were—From measles, 2·1 in Liverpool and in Salford, 2·2 in Manchester, and 4·6 in Huddersfield; from whooping-cough, 1·7 in Birmingham, 1·9 in Oldham, 2·0 in Preston, and 2·7 in Plymouth; from scarlet fever, 1·0 in Manchester and in Salford, and 1·6 in Birkenhead; and from "fever," 1·3 in Blackburn. The 38 deaths from diphtheria included 19 in London, 5 in Glasgow, 2 in Bristol, and 2 in Birmingham. Small-pox caused 3 deaths in Manchester, but not one in London or in any of the other large towns.

WEDNESDAY, MARCH 16, 1887.

PROFESSIONAL ADVERTISING.

Very numerous complaints reach us in reference to alleged infringements of the rules of etiquette which, especially in the medical profession, put a formal veto on appeals to the public by means of advertisements. Now, advertisement is a very vague name for a very common, but none the less reprehensible proceeding, and the essence of the misdemeanor lies in doing it in ways that are derogatory to the individual and to the dignity of the profession to which he belongs. It is difficult and even impossible to lay down a definition which shall explain exactly what is comprised under this term, and still more so to find a line of demarcation which shall separate the venial, because general advertisement, from the variety which should subject the offender to the pains and penalties in that case made and provided.

In the law, a large amount of publicity is obtained merely by the performance of one's duty, although the more astute members of the legal profession know very well how to improve the occasion and obtain a notoriety not always commensurate with either their position or their abilities. The doctor works in a more secluded sphere, it is only exceptionally that he appears before the public at large in his professional capacity, and then not always to his advantage, thanks to the abilities of his adversaries to discountenance and misinterpret his actions and their consequences. To the young and struggling man, therefore, the temptation to obtain advancement by self-advertisement in one or other of its various forms, is very great, and to it a regrettably large number succumb. Not that many men recklessly throw themselves into opposition with the regulations of their particular licensing bodies; to do so is the act of a foolish or an ignorant man but, while still within the limits of the written law, they ruthlessly violate its spirit and thwart its intentions.

On examining the matter closely, one is struck by the difference with which the self same act is viewed by the profession according as the delinquent—for he is always a delinquent—is high up or low down in his department. Many of the instances of unblushing advertisement of the kind which we have alluded to as legal but improper, are to be traced to men whose position in the profession and socially, should place them above it. Passing by the alacrity with which the men who are fortunate enough to have for patients, members of the *classes dirigeantes*, sign and issue bulletins of the condition and progress of their patient, it is impossible to view the wholesale advertisement in the lay press, of books, good, bad, and indifferent, addressed or not to the public, as anything else than complacent self-advertisement. The example is so frequently given in high places that it is positively invidious to single out for disapprobation the humbler brother who does, on a small scale, what his more successful *confrère* does wholesale. That the practice is reprehensible and contrary to the spirit of the law there can be little difference of opinion, but, when the censors of professional conduct themselves lead the way, it is no wonder if hungrier men endeavour to emulate a practice which has undoubtedly contributed in no small degree to the *vogue* of many of our great men.

The great man, too, gets much of his advertising done for him for nothing by a tribe of admirers, who, from faith or interest, blazon his virtues and his skill *urbi et orbe*. This has the immense advantage of allowing the adulated person to disclaim all responsibility, and even affect to dislike the very means to which he owes his celebrity. He may be or becomes a lecturer, and then not unfrequently his lectures, whatever else they may contain, do not fail to put in relief the sagacity and skill of the lecturer. The recital of other people's errors only render his own perfection more patent.

The miserable little devices of his humbler brother seem ridiculous after such an exhibition, and are treated with the contempt which they undoubtedly deserve. What is wanted is a higher conception of the duties of one's profession in this respect. A man who transgresses a tacit convention of this kind even in the intention, is guilty of taking, or endeavouring to take, a dishonest and unfair advantage of his fellow professionals who are simple enough to abide by their undertaking. It is this feeling which gives rise to the dislike which men feel when prominent examples of this description of offence are brought to their notice. No legal repression would probably be of avail against this violation of professional etiquette; only the pressure of public opinion will ever do anything towards restraining men, whatever their position, from advancing their interests by the best way in their power, careful only not to lose the fruit of their labour by too tangible a departure from the normal lines of conduct. But there must not be two sets of weights and measures, one for the use of the great and powerful, and the other for the especial advantage of the poor and struggling. It is derogatory anywhere, but it is doubly so when the daily bread is no longer at stake, and the morrow can be looked forward to with complacency, and without apprehension.

THE IRISH APOTHECARIES' HALL AND THE CONJOINT SCHEME.

We have received for publication the following correspondence between two distinguished Fellows of the Irish Colleges of Physicians and Surgeons, and—under existing circumstances, and considering the importance of the questions involved—we feel that no apology from us is necessary for devoting considerable space to their publication. The practically unanimous decision of the College of Physicians not to regard the persuasion of the Medical Council, the invitation of the College of Surgeons, or the voice of public opinion has narrowed the controversy and brought near the settlement of the Irish conjoint examination question. The College of Surgeons put before the Physicians a choice of alternatives, either to admit the "Hall" to a tripartite conjunction, or to stand by and see the formation of a second and competing conjunction between the Surgeons and the Apothecaries. They have advisedly rejected the first alternative, and we cannot see that they have any choice but to accept the second. From Clause 2 of the new Medical Act the College of Surgeons derives power to enter into any number of conjunctions collateral to that with the College of Physicians, and we do not believe that there is any shadow of foundation for the idea that a contract of either law or honour has been entered on by the College of Surgeons which might debar it from forming a second conjunction.

It is scarcely necessary to say that we regard the double conjunction as an alternative greatly inferior to the tripartite scheme, but it is equally superior to the proposition to leave the "Hall" to stand out as an independent qualifying body. We feel obliged to say that the Fellows of the College of Physicians have displayed a childish weakness of policy in this matter. Instead of looking facts and probabilities in the face, they have clung to puerile interpretations of the law, far-fetched hypotheses as to their own and the "Hall's" status, and forlorn hopes that the Medical Council, or the Privy Council, or some unlooked-for contingency would stand between them and the inevitable. Even still there are, we believe, some of the Fellows who count upon being able to induce the Medical Council or Privy Council to refuse the "Hall" its assistant examiners in case it is excluded from conjunction. We will not discuss such an unsubstantial illusion, but we take the occasion to warn them that disestablishment and disendowment has, by the contumacy of the College, been brought much nearer to its doors than to the doors of the despised "Hall."

The following is the correspondence to which we have referred: —

My dear ——,—I cannot tell you how concerned I am at the move to institute a double conjoint examination, namely, the one already nearly perfected between the Colleges of Physicians and Surgeons and another between the College of Surgeons and the Apothecaries' Company. You know well that I am not actuated by any extreme hostility to the Apothecaries' Company, for under existing circumstances I am in favour of admitting it to a share in the Conjoint Scheme which our two Colleges are about to establish. You also know that I am far from being hostile to your College, for for twenty years I have constantly advocated the junction of the two Colleges for examination purposes, on the basis of existing scale of fees, but I feel that the dual scheme now proposed is fraught with great injury to your College and to the status of the profession in Ireland. The idea of the College of Surgeons adopting the proposed plan is far from being received with disfavour by some of the Fellows of the College of Physicians, but it is probable that these men will assert that the College of Surgeons was ready to make any terms calculated to be of pecuniary advantage to them, and will say, "See, we were right, the College of Surgeons will do anything to make money." It is not what you think, but what the public will believe, that is of importance. I cannot but fear that in the present instance your usual good judgment is influenced by the annoyance you feel at the refusal by the College of Physicians to admit the Apothecaries' Company to a share in the conjoint examinations, and I beg of you to consider well the step you think of taking before it is too late, for I am sure you will live to regret it. Pray excuse my writing thus freely, but I desire the welfare of the College of Surgeons not less than that of my own College.

I am, yours sincerely,

March 7, 1887. F.K. & Q.C.P.

Dear ——,—Thanks for your letter, which I have thought over very carefully.

Of your anxiety for the public welfare and of your loyalty to the profession and to both Colleges no one is more fully aware than am I myself, but it seems to me there are some points in reference to the proposed dual combination between the College of Surgeons and the College of Physicians on the one hand and the College of Surgeons and the Apothecaries on the other to which you have not given due weight.

As to what may be said by the clique to which you allude as to the College of Surgeons being ready to stoop to mean devices for making money, if the character of the College will not enable them to treat such vulgar abuse with the contempt it deserves, the sooner it loses its existence the better. I am sure neither you nor any man whose opinion is worthy of consideration would join in such an outcry.

The important question is as to what, under present circumstances, is best for the public welfare and for the profession at large.

On this question there is not much difference between you and me so far as I can see.

I believe the Apothecaries are legally established as a licensing body with authority to grant a licence in medicine, and as such entitled, under the Act of 1886, to enter into a combination with a surgical corporation to grant a registrable diploma, and, failing this, entitled to have assistant examiners appointed for them by the Medical Council, which would give them full and independent powers to grant registrable diplomas.

Whether they should have been put in this position is not the question. We have to deal with the fact that they are in this position, and the question is how would this affect the public and professional welfare, and how can we prevent evil arising from their position.

The Legislature passed the Act of 1886 for the purpose of effecting a combination, and our Colleges acquiesced in the passing of it, in so far that they did not oppose it, which seems to me to imply a contract to carry out the Act. The College of Surgeons used their best endeavours to induce the College of Physicians to admit the Apothecaries into combination. They urged the formation of this tripartite combination on the ground that the establishing of the Apothecaries as a separate licensing body would lead to the lowering of the standard of education, and so be injurious to the public welfare, but the College of Physicians objected so strongly that the College of Surgeons yielded, and a combination of the two Colleges was agreed on. The scheme for this combination was, in accordance with clause 19 of the Act of 1858, sent to the Medical Council for their sanction, and they referred it back with a strong expression of hope that it would be reconsidered with a view to admitting the Apothecaries.

The College of Surgeons again urged that the Apothecaries should be admitted, and stated that, failing that, they would be willing to maintain the combination already entered into with the College of Physicians, and to enter into a separate combination with the Apothecaries.

In this they proposed following the precedent of the Scotch Corporations when the College of Physicians combined with the College of Surgeons, and entered into a second combination with the Faculty of Physicians and Surgeons of Glasgow This arrangement in Scotland, after existing some years, has resulted in the formation of a single tripartite combination, and our College entertained a hope that the same result would, in a little time, be arrived at in Dublin. We also hoped that, by effecting this combination, we could prevent any lowering of the standard of education and examination, and any serious competition as to fees for diplomas. We thought we would thus be doing what was best for the public welfare, and for maintaining the honour and dignity of the profession, and, notwithstanding your arguments, it still seems to me the right course to be adopted.

I have looked carefully into clause 2 of the Scheme, in reference to what you said in our conversation on Monday as to its debarring us from entering into the proposed dual combination. This clause was intended to deal with the cases of registered practitioners of three classes, viz.:—

1. Men seeking higher degrees.
2. Graduates of Universities wishing to have the licences of, and associate themselves with, either of our Colleges.
3. English, Scotch, colonial, or foreign practitioners anxious in the same way to have a licence or be associated with us.

Any other application of this clause would, I think, be a straining of its meaning and intention, and a misapplication. I do not see how it could affect the question of the proposed dual combination in any way.

I have written at length in the hope of making my views understood, and am sorry I could not express myself more briefly.

Yours very sincerely,

March 9, 1887. F.R.C.S.I.

Sir,—We are quite in accord on the main point, as to what would have been the best course, but as my College absolutely refuses to admit the Hall we take different views. You think you, by joining with the Apothecaries, will elevate them. I believe, on the contrary, that by degrees you will be lowered to meet what is their standard, and that you will have two classes of licentiates who will be antagonistic to each other, viz., those who hold the College of Physicians and Hall licenses respectively. You need not hope that the public will esteem them on an equality, for the former will take good care they will not. I believe you will establish a low grade of mongrel qualification. If the Council give the Hall Examiners (or one examiner only as they ask) these licentiates will be fully qualified no doubt, but they will with equal certainty be esteemed of an inferior rank. The number of candidates will not be very numerous, and I hold that there will be quite as much, or more chance of a permanent amalgamation than by your scheme, but even if there be not, I do not think we should do wrong that good may come. The analogy in Scotland is not perfect, the Glasgow body was not a joint stock trading body, keeping open shop, and the College of Physicians had no rights over them, such as the College of Physicians has, which rights clearly indicate the subordination of, not inferiority of, the Hall. There is no doubt but that every Fellow of the College of Physicians, who thought of the matter believed when the clause I referred to was being considered, that we were entering into an agreement, excluding the junction, directly or indirectly, of any other body. Of course, I do not know what were your ideas. I know I spoke to that very clause, and advocated it, on the idea that, that was its force; and I cannot oppose the demand which will now be made for the reconsideration of the whole scheme. We will say your college refuses, or that the scheme falls through, and that we are refused examiners by the Council, we appeal to the Privy Council, and I doubt if they will disenfranchise us when we show that we merely asked for re-constitution and re-adjustment when a fundamental principle is violated; suppose we fail, will it be for the benefit of medical education that we be wiped out? I feel quite sure that the solution of the question by the means you advocate is not a wise one. I write freely because I know you have sincerely the well being of the profession at heart, and fully acquit you of any desire to promote the monetary interest of your college by unfair or improper means, and without doubt the free circulation of such a statement will lower our profession in the eyes of the public. They will say it is another battle of the shops for customers. My college is greatly encouraged by the action of the London Colleges, whose case is not so good as ours.

No person whatever is aware of this correspondence. I have never alluded to my communication with you to any one. We are simply two friends who equally desire to do right, but look at the question from different points. I have desired to put my views before you, which I cannot do at your Council table, and nothing but my anxiety for the welfare of my profession, would induce me to bother myself by thinking over the matter, as I have done of late, for I have become most adverse to all forms of politics. Your letter is very clear far more I fear than mine, but if you can gather my meaning it is all that is needed.

I am, your very sincerely,

March 9, 1887. F.K. & Q.C.P.

THE LUNACY ACTS AMENDMENT BILL.

This Bill has had a chequered career in the House of Lords. It has been dissected and reconstructed year after year until the result arrived at is one of inextricable confusion, ill-digested enactments and vague ideas as to how it can possibly work. Each Lord Chancellor has left his individual mark upon it only to serve a temporary purpose and to be obliterated by the mark of his successor, and we find present and past Lord Chancellors disagreeing on vital principles, and a weak compromise giving place to what was a strong measure for good or ill. On its last appearance in the House of Lords the Lord Chancellor offered to amend sub-section 11 by inserting a provision into it to the effect "that where a person has been sent to an asylum or a private house and has not been visited by a county court judge or a magistrate having jurisdiction there, the person confined shall have a right to be seen by such." This compromise did not satisfy the Earl of Selborne or Lord Herschell, and the discussion arising out of it showed that it was ill-considered and unworkable. Indeed, the more we read of the lunacy discussions in the House of Lords the more hopeless seems the ignorance and confusion of those to whom is entrusted the responsible task of legislating on the subject. The Bill has been hammered at from all directions, and it seems impossible to lick it into shape, so as to please all parties; in fact, it has been a hot coal to successive Lord Chancellors, and each in turn is doubtless glad to get it off his hands with all possible despatch. It is one of the melancholy signs of our times that public affairs, and especially medicine in its public aspect, are handled more and more by amateurs to the exclusion of experts, and there can be no doubt that in giving so much legislative powers to the lawyers in the House of Lords, a decided non-medical bias is given to the construction of the Bill. The Lord Chancellor, for example, is either so obtuse or so ignorant that, to use his own reported statement, "he did not know why an examination before a magistrate should be more injurious to a lunatic than the investigation which medical men were supposed to make before signing a certificate for his removal, and he could not understand why a magistrate should not be competent to decide the question with a judicial mind as a medical man. The magistrate would determine the question not solely by his own view of his power of detecting mental disease but in the ordinary way in which he determined any matter which came before him in his judicial capacity." Here is the point where Medicine and Law diverge. Medicine recognises disease and disease only, and is competent alone to diagnose mental disease. It recognises the necessity for prompt treatment, quiet, unexciting methods of procedure, and the treatment of the patient deprived not of his liberty so much as of his healthy mental action. The question of liberty is so aggressively introduced into every phase of this lunacy question that there is a danger by no means imaginary of developing *traits* of lunacy of a correspondingly aggressive character, of multiplying and accentuating morbid suspicions, delusions of persecution and of evil designs on the part of relatives and friends. With the idea of imprisonment which a cumbrous and semi-public mode of committal implies to a sensitive mind, the beneficial influences of an asylum give place to what is baneful, and recovery is retarded, if not rendered impossible. Law recognises mental disease in so far only as it is a social or medico-legal question, and is more readily guided in its so-called diagnosis by the haphazard teaching of common untutored experience, by individual proclivities on the part of the judge or magistrate, and by the hue and cry of public opinion that is most loudly heard in the political atmosphere. If judicial decisions were as free from error as the medical diagnosis of insanity has been, there might be some occasion to throw stones and to sneer at the diagnostic capacity of Medicine. Our profession is the wisest friend in this matter, not only to the individual who suffers from mental disease, but to society at large; for with a minimum of risk, it procures speedy treatment for those who are mentally afflicted, and it regards publicity as inevitably calculated to weaken the mental stability of a recovered lunatic when he subsequently realises what he has passed through.

Notes on Current Topics.

The Etiology of Scarlet Fever.

The chain of evidence connecting human scarlatina with a certain disease (as yet unnamed) occurring in milch cows has been made remarkably complete and unbroken by the renewed researches undertaken for the Government by Dr. Klein. It may be remembered that a specific and distinct micrococcus was isolated from the ulcers of the cow, and that this when inoculated into calves, produced morbid lesions exactly like those of the cows at Hendon, and those usually found in human scarlatina. During the present winter, Dr. Klein has examined the blood of scarlatina patients at the Western Hospital, Fulham, with the result of finding in it a micrococcus identical as to growth and cultivation with that obtained from the cows' ulcers. He further found that on inoculating and feeding mice with the two sets of micrococci, viz., Hendon and Fulham, the same pathological results were produced And, lastly, cultures were established from the blood of mice which had perished after these inoculations; and these were found to contain the same micrococci again, growing in exactly the same manner. Similar inoculations were made on calves, who developed similar lesions to those affecting certain calves inoculated with the Hendon micrococcus last year; and from the heart's blood of these the same micrococcus was recovered by cultivation as had been found in the Hendon cows' ulcers and the fever patients' blood. Thus, then, the circle has been fully drawn; and a valuable discovery lies enshrined within it, one which reflects the greatest credit upon the perspicacity of Mr. W. H. Power, who made clear the circumstantial details of the Hendon outbreak, as well as the skilful and philosophic experimentation of Dr. Klein. But the practical importance of this newly observed relation between scarlatina and cow-disease transcends its mere scientific aspect, for there is obviously power by careful supervision of herds and of dairies to limit and curtail the action of the most blighting influence against which our youthful population has to fight.

Nine Hours' Artificial Respiration.

Reports from Ceylon contain an interesting description of recovery of consciousness of the taxidermist of the Victoria Museum who was bitten by a cobra, which he thought harmless, from previous extraction of the poison bag. For a few moments after the bite he took no heed of it, but pain and nausea were soon set up. Carbolic acid was then applied, ligatures were bound round the arm, an incision was made at the bite, and the blood of the arm was wholly removed. Various antidotes were used, but the unfortunate man lost the power of speech, and soon every muscle became paralysed, and respiration ceased. Artificial respiration was then resorted to, and this operation was unceasingly continued for nine hours, when at last the patient made an attempt to breathe, and soon regained consciousness enough to make his wants known. He steadily improved until Friday, the accident having taken place on Wednesday, and then astonished those around him by stating he was conscious of all that had been taking place, but was unable to make his feelings known, not having the power over a single muscle. It would seem that the poison paralysed the nerves of motion, but not those of feeling, for he could see and hear and feel, although the attending physician, even by touching the eyeball, could get no response either of feeling or consciousness. His partial recovery was, however, followed by a high fever and inflammation of the lungs, and he died, perfectly conscious, on the following Sunday.

Sir Walter Foster, M.D., one of the Direct Representatives on the General Medical Council, formerly M.P. for Chester, has been invited, and has consented, to contest the Ilkeston Division of Derbyshire, in opposition to Mr. Leeke, the Conservative candidate.

Absorption through the Skin.

A further contribution towards clearing up the uncertainty which exists on this subject, has been made by Messrs. Ritter and Pfeiffer (*Med. Chron.*). Their method was to rub well into the extensor surface of a healthy limb half an ounce of an ointment containing the substance under investigation, then to cover the spot with a bandage to prevent any possible absorption by the lungs, and after twenty-four hours to collect some urine and examine it. It was found that potassium iodide from a 10 per cent. ointment passed into the urine in only one out of five cases, and this was after the ointment had been used for four days, when the skin had become irritated and its continuity practically destroyed. Sodium salicylate applied in the same way was never found, even in traces, in the urine; but salicylic acid gave its test within a few hours after its application. This is attributed to the property possessed by it of softening the epidermis, and if the application of salicylic acid ointment was followed by one of potassium iodide ointment, the potassium iodide quickly became detectable in the urine.

The Procuring of Abortion.

In all large cities the trade of procuring abortion is one which almost inevitably obtains a footing; the footing, it is true, is insecure, but the occupation is probably remunerative. Fortunately for public morals, persons possessed of the requisite skill are rarely disposed to have recourse to such a questionable means of gaining a livelihood, and the others sooner or later fall into the hands of the police. Last week Dr. G. Danford Thomas held an inquest on the body of a woman who was taken ill on February 11th, being then pregnant, and died on the 22nd. The medical man in attendance gave a certificate, and the body was about to be buried, when information was given to the coroner, who ordered a special examination by Professor Pepper of St. Mary's Hospital. This gentleman certified that death was due to pyæmia consequent on lacerations following an attempt to procure abortion. Both the husband and the medical attendant of the deceased woman were ignorant of any operation having taken place. So far the police have been unable to trace the deceased's movements, but it is to be hoped that this may ultimately be done. The position of the medical man in such cases as these is full of difficulty. He is called in to a woman, let us say with general febrile symptoms, who of course does her level best to put the doctor off the track, very often with success. As the malady progresses, the doctor, baffled in his attempts to arrive at a diagnosis, by deliberate misstatements as to the site of pain, &c., falls back on typhoid fever, meningitis, or some other disease, the symptoms of which are not altogether at variance with those presented by his patient. Unless the patient voluntarily or unconsciously allows the real circumstances of the case to transpire, or the doctor be a man of unusual astuteness and sagacity, the facts, whatever the termination of the case, remain a secret, known only to the parties immediately concerned. It is so difficult during life to be absolutely certain of one's diagnosis in such cases, that it is no wonder if men prefer the easier course. Nothing can be so objectionable as to make an unjustifiable accusation of such an abominable offence, since it is even more difficult to disprove than to prove.

Quack Advertisements.

It is with some astonishment that we see in both of our medical contemporaries an advertisement of the "Art of Massage," by Donald Maguire, an individual who was erroneously described in some recent proceedings in the police-court and elsewhere, as a medical man, to the great scandal of the profession. The mere insertion of the advertisement of an unqualified man, writing on a quasi-medical subject, is in itself an innovation, and not by any means one that can be commended. It would be comforting to know exactly what code of ethics the proprietors or editors of the journals referred to, profess to follow. Now they have inserted this advertisement it is difficult to see where they can draw the line without rendering themselves liable to a charge of gross inconsistency. The irregular practitioners who, hitherto, have confined their operations to the columns of our religious contemporaries, will do well to forward their puffs to the respective journals. Their offers can scarcely be refused if accompanied by a cheque for the amount due, and if their advertisements were declined, they would be justified in animadverting severely on the partiality of the censure, which admits the advertisement of one quack, and refuses that of another. The now notorious Mrs. Longshore Potts who undertook to familiarise our young ladies with American notions of practical physiology, experienced no difficulty in obtaining insertion of her announcements, although as events proved her intentions, if excellent, were distasteful to the public. The habit of straining at the gnat after having swallowed the camel is a habit which is lamentably common, but it can never be either graceful or becoming.

"The Puff Oblique."

Some time since we found it necessary to draw attention to the small vices that disfigure our medical societies, and the homily on "Little Foxes" appeared with, we are glad to know, good results. It is only by careful watching that the more bold "toats," who by their manifold devices bring discredit on medicine, are kept in check. The paths to honour in the art of medicine are narrow, and are but poorly macadamised. Oft has the weary toiler to rest until renewed strength gives him strength to pursue a journey which love drove him to undertake. How many noble spirits have broken down under the toil? Anstie, Mahomed, Moxon, and others occur to the medical mind, and we cannot but regret that too often the honest worker and the most gifted of the sons of medicine die unrecognised and unrewarded. But also there is a swarm of miserable beings, who, either from their own ambition or from pride of their relatives have donned the livery of medicine for worldly considerations, and who seek to attain notoriety and wealth by short cuts. Forbidden by the profession to advertise in the lay press, they exert the little brains which such a fraternity usually possesses to circumvent the plain purpose of the rule and contrive by personal friendships, &c., to make the law a nullity. Knowing the good-will of the press is the "sesame" to popularity these gentry adopt many and devious devices to secure that favourable mention. And on the waiting-room table in due course are to be found, with the paragraph "puff" prominently marked, several copies of the particular newspaper, until manipulation has worn them to tatters. To particularise special offenders is not within the limits of our duty. Such should devolve on the College to which the offending member belongs, and recently the College of Surgeons has shown themselves so quick to protect the fair fame of medicine, by punishment of licentiates who allowed their names to be advertised in the lay press in connection with quack remedies, that it is to be expected that one of the Colleges will remind one of its Fellows that a notice which recently appeared in a "pictorial" paper is on the border land of advertisements, and reads suspiciously like a "puff direct," though we in charity have selected to consider it under the heading of the "Puff Oblique."

The Sanitary Condition of Windsor.

Owing to certain remarks that were made in a contemporary last year concerning the sanitary state of the Royal Borough, an inquiry has recently been conducted by a medical and an engineer inspector of the Local Government Board, who made a careful investigation into the state of the place, at the request of a local deputation representing the various parties and interests involved. The report of the two inspectors has been recently issued and is before us. It will be seen from perusing this document that, though there is agreement in the main with the assertions of the so-called "Commissioner" of our contemporary; yet, as the inspectors themselves justly conclude, Windsor is, if anything, in a better sanitary condition than innumerable other old towns, and that judgment should not be hastily passed upon public bodies who are inheritors of the shortcomings of the pre-sanitary era, when public health acts and bye-laws were unheard of. It is indeed somewhat hard that Windsor, from its very favoured associations, should have been pitched upon for the unmitigated strictures that were lately passed upon it. But, on the other hand, Windsor may have intercepted some beams of the "Fierce light that beats upon a throne," which causes more to be expected of her than other less fortunately favoured places; and therefore there is now an opportunity, by attention to the recommendations appended to the official report which has recently appeared, to truly merit her prominent position. The points to which particular notice would appear to have been directed are the improvement of the ventilation and air space of the poorer quarters of the Borough, under either the Public Health Act of 1875 or the Artizans' and Labourers' Dwellings Improvement Acts; the appointment of a separate nuisance inspector, instead of combining this office with that of borough surveyor; the provision of hospital isolation and proper disinfection, as well as of a destructor for house refuse. We trust to the good sense of the Windsor corporation to see that these reforms are speedily carried out.

The London Hospital and its Students.

A curious, not to say, very unfortunate, degree of friction is at present prevailing between the students and staff at the London Hospital. Indeed, if rumour be correct, a campaign of rustication is to be instituted by the latter in order to attempt to relieve the existing state of things. A radical treatment, forsooth, and necessary perhaps in certain cases; but what have the students to say in defence of their conduct? Briefly it is as follows: Certain resident appointments which, in the ordinary course of things, are always considered in medical schools, more or less, as rewards for diligence and conspicuous merit, have recently at the London Hospital been handed over to outsiders, men possessing university degrees. With reason and right on their side the students have openly remonstrated, complaining of the "jobbery" which has been perpetrated, and regarding the action in question as an unwarrantable violation of the established custom, which has hitherto obtained, of choosing medical students or junior qualified men of the London Hospital to fill the vacancies. The line which the students have taken up is receiving more or less support from some members of the staff, and this shows at once how deplorable will be the results to the school—if not even to the best interests of the hospital—unless measures are speedily adopted to undo the harm which has been done, and meet the difficulties of the case by the exercise of justice, foresight, and tact. When a surgeon, about to visit his wards, is met by a large body of students, publicly hissed, and then deserted, and left to plod his weary way round his wards by himself, surely the time has come when a searching inquiry should be made into the grievances which are said to persist. It is doubtful whether a hospital which obtains an unenviable notoriety ever afterwards recovers the ground in public estimation, which it may lose in consequence. It is to be hoped, therefore, that the points in dispute at the London Hospital will be harmoniously adjusted before this undesirable contingency can occur.

The Unqualified Assistant and the Death Certificate.

A somewhat remarkable occurrence is reported from Tinsley in reference to the death of a child, three years of age, on whose body an inquest was held on Wednesday last. A certificate purporting to have been given by Mr. Dearden, surgeon, of that locality, had been handed to the Registrar to the effect that death was due to epilepsy and convulsions. By some curious error the Registrar entered the death as due to "a fall eleven months ago," which presumably led to an inquest being held. It was rather fortunate that this was so, for it transpired that the certificate in question had been given, not by Mr. Dearden, but by a Mr. Branson, his unqualified assistant, who had imitated his signature with a talent worthy of a better cause. Mr. Dearden's explanation of this odd proceeding was that it was the result of a misapprehension of his instructions; but the Coroner very curtly intimated his scepticism as to the possibility of this having been the case, and declared his intention of bringing the circumstances under the notice of the Registrar-General, who will doubtless take the necessary steps to impress Mr. Dearden and his assistant with the desirability, not to say the necessity, of greater attention in the giving of death certificates. A post-mortem examination of the body of the child, made by Mr. C. Atkin, proved that death was attributable to tubercular meningitis. The error in diagnosis is a matter of comparatively trivial importance, but medical men cannot be too strongly impressed with the necessity of giving death certificates with the care and accuracy which their nature requires.

Resignation of Sir Michael Hicks-Beach.

The certificate which has been published in reference to the reasons which have decided Sir Michael Hicks-Beach to resign his portfolio is couched in language which strikes one as curious, to say the least of it, on the part of its signatories. Attention is called to the fact that the unfortunate ex-Minister has a "cataract *on* either eye." We should be glad to know if this is to be considered the correct way of describing this affliction in "either" eye. It is on a par with the context, which bears the appearance of being studiously ambiguous. It is satisfactory to find that his dimness of vision, though due to cataract, has become much less, and that Sir Michael is now much better in health and sight.

A New Pharmacy Bill.

A Bill has been introduced in the House of Lords by the Earl of Milltown, under the title of the "Pharmacy Acts Amendment Bill," to amend the Pharmacy Acts of 1852 and 1868. The object of the Bill is to introduce sundry modifications into the curriculum of pharmaceutical students, the supervision of which would be entrusted to the Pharmaceutical Society of Great Britain. It is not intended to apply to Ireland.

The Margaret Street Infirmary.

At the last meeting of the Medical Board of the North London Hospital for Consumption a resolution of sympathy with the resigning members of the above institution was passed, a copy of which was directed to be forwarded to Dr. Hawksley, the late senior consulting physician to the Infirmary, with a request that he would convey the substance thereof to his former colleagues.

"Jacob Testimonial."

We are requested to remind intending subscribers to this fund, which has now amounted to nearly £500, that the list will be closed on Monday, 21st inst. The Hon. Secretaries will be obliged if subscribers will point out any inaccuracies which may have occurred in the lists published weekly in the medical journals.

A Correction

We are requested to state that the David Thomas charged last week with illegal assumption of the title of "Dr.," does not reside as stated in Rye Lane, but at Peckham Rye. This correction is rendered necessary by the fact that a genuine Dr. Thomas does live in Rye Lane, and he is naturally very anxious that no confusion should be allowed to exist as to the identity of the culprit. Q.E.D.

M.D.'s. for London Diplomates.

We understand that the action taken by the Irish Colleges, in claiming that all powers taken by the London Colleges to grant degrees in medicine shall be extended also to them, has been followed up by the Edinburgh and Glasgow Colleges, who have lodged with the Privy Council a *caveat* against the grant of such privileges to the London Colleges exclusively. These movements open up speculations as to a lively passage of arms between the Colleges and Universities of the three divisions of the Kingdom. If the title of M.D. is to be the property of every London general practitioner, it will require a good deal of logic to satisfy Parliament and Government that it is not equally the right of Scotch and Irish diplomates.

The Irish Medical Association.

Dr. Jacob has considered it incumbent on him to resign his seat on the Executive Committee of the Association, and his resignation—being persisted in after a request for its withdrawal—has been accepted by the Committee. The cause of Dr. Jacob's retirement from the working of the Association with which he has been intimately associated for five-and-twenty years, is a disagreement with his colleagues respecting the Poor-law Superannuation Bill. He thought that the present condition of politics offered some hope that a Bill which would be a clear gain to the Poor-law medical officers of Ireland might, by negotiation and compromise, be got through Parliament, and having made inquiries, he was encouraged in this hope. He therefore moved the committee to open up (or to allow to be opened up) *pourparlers* with the Irish Members whose hostility had defeated the Bill three years ago, with the object of ascertaining on what, if any, terms, they would allow such a Bill to pass. It would have then remained for the Association to say whether such terms would be any improvement on the existing state of things. The committee—for reasons which no doubt they understand—did not consider the occasion opportune for taking any action in favour of Poor-law medical superannuation, and therefore declined to enter on negotiations with the Irish Members. Dr. Jacob, on the other hand, is strongly of opinion that the opportunity is not likely to be more promising for any number of years to which Ireland can look forward, and he is not prepared to acquiesce in the postponement, not only of the Superannuation Bill, but of all the Parliamentary work of the Association (which has been his special department of work), until an indefinitely distant change in the political *status quo*. He therefore felt it necessary to resign his Committee seat, and any future action which is to be taken on the subject must be either in the Council of the Association or in the general meeting of its members.

A conference of gentlemen and ladies interested in the extension of University teaching will take place at Oxford on Wednesday and Thursday, April 20th and 21st. The Bishop of London will take the chair at the first, and Dr. Percival at the second meeting of the conference.

Grievances of Army Medical Officers.

The President and Council of the Royal College of Surgeons in Ireland have sent the following Petition to both Houses of Parliament. Lord Ashburne has presented it to the Upper House, and Dr. Cameron, M.P., to the Lower:—

The Petition of the Royal College of Surgeons in Ireland.

Humbly Sheweth—That your Petitioners, having been charged by Charter with the duty of "providing a sufficient number of properly educated Surgeons for the service of the Army," are concerned to represent that the Medical Officers of Her Majesty's Army suffer under substantial grievances deserving of consideration and redress by your Honourable House.

That Medical Officers entering the Army Medical Service are placed at a disadvantage as compared with Officers of similar rank and seniority entering the Indian and Naval Medical Services, inasmuch as their commissions do not date from the period at which they have passed the examinations necessary to their admission, but from a date subsequent to their period of service in the Army Medical School.

That Officers of the Army Medical Staff when ordered to service in India are not allowed the pay granted to other officers of the rank which they held under Her Majesty's Warrant, their monthly pay (under five years' service) being R317 8 0, to include all expenditure from transport and field duty, as compared with R415 6 0 *per mensem* allowed to combatant officers of the same rank under similar circumstances.

That Army Medical Officers suffer great injustice from the fact that, when incapacitated by disability incurred by and in the discharge of their duty, they are not allowed, as combatant officers are, to count all their sick leave (beyond a period of six months) towards seniority, and are not entitled to pension or gratuity of equivalent value to that granted to combatant officers of their rank.

That, if Army Medical Officers become so incapacitated before the tenth year of their service, they are not entitled, under the terms of Her Majesty's Warrant, to receive any pension or gratuity equivalent to that granted to other officers of similar rank.

Your Petitioners, therefore, humbly pray your Honourable House to take such steps as may be necessary to cause the Medical Officers of Her Majesty's Service to be placed in the same position, in these respects, as that occupied by other officers of equal rank and period of service.

And your Petitioners will ever pray, &c.

William Stokes, Knt., *President.*
Anthony H. Corley, *Vice-President.*
Archibald H. Jacob, *Secretary of the Council.*

Mr. Howse, F.R.C.S., of Guy's Hospital, has been elected on the Court of Examiners of the Royal College of Surgeons of England.

The consideration of the request of the General Medical Council to admit the Apothecaries' Society to the joint examination of the London Colleges has been deferred by the Royal College of Surgeons to the extraordinary meeting summoned for the 24th inst.

If the work done by the General Medical Council bears any relation to its cost, the millennium in the matter of medical education is near at hand. It was stated by Dr. Quain, who, in his capacity of chairman of the Finance Committee, ought to know, that, taken altogether, the expense of the Council averages £1 per minute. Even this statement did not have the desired effect of checking the irrelevant loquacity of sundry members, whose aim in life would seem to be to raise and prolong a futile discussion on points of order or disorder. The system of paying these gentlemen by fees is radically bad, and should be modified.

At the Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The existence of a form of parotitis of gouty origin, and which subsides on the outbreak of the gout in localities such as the knee-joint was described at the last meeting of the Medical and Chirurgical Society, in a paper which was communicated by Dr. Garrod, F.R.S., the author being Dr. Debout D'Estrées. In the discussion which followed the reading of the paper, Sir Dyce Duckworth remarked on the absence from medical literature of any records of such affections of the parotid, and referred to Sir James Paget's observation to the effect that the lymphatic system as a rule escaped gouty injury. Sir Dyce, however, had no doubt of the correctness of Dr. D'Estrées' diagnosis, and the succeeding speaker, Mr. Stephen Paget, was able to adduce an instance in support of it, as the result of a search extending over the records of 100 cases of parotitis. Dr. Garrod also, who spoke after Dr. B. O'Connor had made a few remarks, was able to recall 100 cases of the affection in gouty subjects. In neither did suppuration occur, profuse salivation being the mode of their termination. Out of two thousand cases of gout, however, recorded in his private note-books, he could find nothing to show that the symptoms observed included any connected with the parotid glands. In replying on the discussion, the author of the paper mentioned a second case, which occurred in the practice of his friend Prof. Damaschino, of the Hôpital Laennec, Paris, also a woman, in whom double parotitis subsided on the onset of gouty inflammation of the knees.

A very animated discussion next ensued on a paper for which Dr. W. Ewart and Mr. Fitzroy Benham were jointly responsible, and detailed the history of a case of empyema with pulmonary gangrene following enteric fever, and treated by perflation. The patient was a boy of ten, who contracted empyema when convalescing from typhoid fever. Aspiration was first employed, and later a free opening made into the chest in front and behind. No injection was used, but, under the spray, perflation of air, by aid of which not only pus, but also a piece of necrosed lung and some heavy membranes were discharged. The President, Mr. G. Pollock, was unable to see that the plan proposed possessed advantages over that he himself had been accustomed to pursue for thirty-five years, viz., to make an exploratory incision first, and then, if pus was present, a free opening. Sir Dyce Duckworth advocated treatment by opening and counter-opening and drainage, reserving the plan of perflation for such cases as did not otherwise do well. Mr. Godlee recorded his preference for iodoform blown into the cavity to get rid of suppurating residual matters; but Mr. Howard Marsh, at a later period of the discussion, declared himself suspicious of iodoform, believing that it might exert a toxic effect, although he approved of free opening into the cavity and drainage by a counter-opening. Messrs. W. H. Bennett and R. W. Parker gave a support to the method of perflation, which Dr. Drewitt expressed himself unable to understand the possibility of; and Dr. Sansom suggested an improvement on Dr. Ewart's plan for disinfecting the air employed for perflation. Mr. Pearce Gould advised caution in framing conclusions from the single case of Dr. Ewart's, especially as it would probably have recovered if treated in any one of several other ways.

MEDICAL SOCIETY OF LONDON.

Mr. Fenwick read a paper embodying a rather novel suggestion as to a means of checking severe hæmorrhage from the kidney resulting from injury or carcinoma. It consisted in introducing an instrument into the ureter and nipping it so as to give time for a clot to form, the clot being intended to act as a mechanical impediment. The operation had been performed successfully in the case of a man aged 51, who had long suffered from profuse hæmaturia. He died six months later, but unfortunately no post-mortem examination was obtainable. Mr. Morris maintained that plugging of the ureter was likely to be followed by enormous dilatation of the ureter above and of the kidney. Several speakers preferred direct surgical intervention in the class of cases for which the operation was proposed.

Mr. Bruce Clarke read a paper on some conditions of bladder in children simulating stone. The particular condition he referred to was a roughness of the mucous lining of the bladder and its coating with hard gritty particles. He quoted two cases which he had had under his care, where the most characteristic symptoms had been produced, and which had yielded to alkalies, milk diet, and rest in bed. Mr. Parker pointed out that the symptoms of stone in girls were very different from those in boys, consisting chiefly in tenesmus and diarrhœa. Mr. Marmaduke Sheild quoted three cases of pelvic sarcoma in which the symptoms closely resembled those of stone. Mr. Henry Morris pointed out that the condition described was dependent on over-acidity of the urine causing cystitis. When this acidity was corrected the condition disappeared.

The Annual Festival Dinner of this Society was held last week in the Venetian Chamber of the Holborn Restaurant, and was in every respect an unequivocal success. Mr. Brudenell Carter discharged the duties of the chair most admirably, and his capacity as a ready and telling speaker was fully evoked and appreciated. In the toast of the evening, "Success to the Medical Society of London," he spoke of its steady increase both in numbers (now 533 subscribing Fellows) and usefulness, of its work in the past, and the great future that lay before it. He then announced that Dr. Hughlings Jackson had been unanimously elected his successor in the presidential chair, and bespoke for him that cordial sympathy and support which had been so cheerfully vouchsafed to him during his year of office. The other toasts were responded to by Sir Thomas Crawford for "The Army," Capt. Crozier "The Navy," and Col. Edis "The Reserve Forces." To Mr. Bryant was entrusted the toast of "The Houses of Parliament," which he prefaced with an amusing speech, which provoked considerable laughter. To this Col. Duncan, M.P., replied in a very able manner. Dr. Ord proposed the "Medical Corporations," to which Mr. Shillitoe, Master of the Apothecaries' Society, replied. Sir Joseph Fayrer, in a few felicitous remarks, proposed the "Health of the Retiring President," who briefly responded, and then gave as the final toast "The Secretaries," which was suitably acknowledged by the retiring Secretary, Mr. J. H. Morgan, Dr. Samuel West, the senior Secretary, Mr. Bernard Pitts, the new Secretary, and Mr. Poole, the highly respected Registrar.

At the last meeting of the Middlesex Hospital Medical Society for the session, which was held on March 10th, Mr. Victor Horsley gave an interesting lecture on Brain Surgery, with limelight illustrations. Dr. David Ferrier took part in the ensuing discussion. Mr. Edgar Crookshank exhibited several preparations of micro-organisms, and showed the capabilities of an oil-immersion lens constructed of the new boric glass.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

Greenock.—Medical Aid Society.—The annual meeting of this society was held on the 10th inst., Mr. John Scott, hon. president, in the chair. The chairman, in opening the proceedings, referred in feeling terms to the loss which not only the society, but the whole community had sustained in the death of ex-Bailie John Duff. Mr. Duff had been connected actively with the society almost since its foundation. The chairman then moved a resolution expressive of the society's sympathy with Mrs. Duff and family in their sore bereavement. Mr. Wm. Auld, secretary, seconded the motion, which was unanimously adopted. Mr. Auld then read the annual report, which showed that at the end of the year there were 17 males and 25 females—total 42—receiving aid from the society at the close of the year. There were 13 deaths of recipients of the society's relief during the year. Mr. Duncan M'Callum, treasurer, read the financial statement, which showed that the total income for 1886 was £350 0s. 9½d. and expenditure £403 16s. 7d., making a deficit for the year of £53 15s. 9½d. The chairman, in moving the adoption of the report, regretted the condition of the finances, recommending the society to the increased liberality of the public. The election of office-bearers for the current year concluded the proceedings.

Glasgow.—Health of the City.—At a meeting of the Glasgow Town Council, held on the 7th inst., Dr. Russell, the medical officer of health for the city, reported that during the fortnight ending 26th February, there were 522 deaths registered as compared with 488 in the fortnight preceding, an increase of 34, representing a death-rate of 25·9 per 1,000 living in place of 24·2. As compared with the corresponding fortnight of last year the death-rate was 2 per 1,000 lower. The death-rate in the first week of the fortnight was 27, and in the second week 24·8. After adjusting the balance between deaths registered in institutions without and within the municipal boundary, the deaths properly belonging to Glasgow were found to number 514, or 8 less than those registered within it, there being 12 added and 20 deducted. The number of deaths of persons aged below one year was 107, as compared with 96; and of persons aged 60 years and upwards, 86, as compared with 82. Of the total deaths, 46 per cent., the same as in the previous fortnight, were of children below 5 years of age. Of children at school age (viz., 5 to 13 years, both inclusive) there were 40 deaths as compared with 29, viz., 2 scarlet fever, 3 measles, 4 whooping-cough, 1 diarrhœa, 6 consumption, 6 acute diseases of the lungs, and 18 from miscellaneous unclassified causes.

VALUE OF REGIMENTAL SURGEONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—As a medical officer who has served with all branches of European troops, in England as well as in India, I was very much gratified to read the remarks which an experienced general officer—Sir Donald Stewart—recently made at Netley on the subject of the regimental system; and your own comments thereon. The system now in force is undoubtedly good for the medical department, but not, I venture to affirm, so good for the soldier. In civil life the medical practitioner, who for the most part lives amongst his patients and who, in course of time, becomes familiar with their several temperaments, predispositions, and idiosyncracies, as well as—a point of no small importance—with their family histories, is, as a rule, better qualified to prescribe for them in sickness than the physician who sees them, perhaps, only once. And, where a case is submitted for a second opinion, the information as to the antecedents, &c., (supplied by the medical attendant) is of great value to the consultant; who very frequently can do no more than what has been done already. So with the regimental medical officer. A conscientious man, in view to future usefulness, makes a point of knowing all he can about every officer and man in the corps (malingerers too are known): and the longer he remains the more useful does he become as an essential part of the military machine. I was once, when in India, attending a board convened for the purpose of examining volunteers, from a regiment about to return home, for further service in India. An active-looking private, who had volunteered, was about to be rejected on account of a suspicious external abdominal ring. The surgeon of the regiment (who was present) suggested that, as during the previous eight years he had known the man to be endowed with considerable powers of physical endurance, to be a good athlete, and never to be "sick nor sorry," the suspicion might be disregarded; and he was accordingly "passed:"—a result entirely due to the information supplied by the regimental surgeon. A good and acclimatised soldier, who would otherwise have been lost, was thus secured for further service to the state.

Dr. ———, who had been appointed to the temporary medical charge of the —th during the absence on leave of the surgeon of the regiment, was returning with me one morning in my carriage from a committee, to which we had been together. As we arrived near home we met a young officer, who saluted Dr. ———. On my asking the latter who he was, he replied, "I fancy he's one of those —th fellows, but I'm so soon going away (he had then been some months in the station) that it is'nt worth while to try to know the whole regiment." Dr. ——— was a married man.

I could record many instances proving the value of the regimental system. Dr. ——— was by no means justified in the view he took of his position; but his remark tends to show how little interest a medical officer would be *likely* to take in a body of officers if he were not permanently connected with them. Nor under the present system is it pretended that he would. The regimental system is useful in other ways. For example, every effort should be made to attach a soldier to his regiment:—he should look upon it as his home. The success of such efforts will greatly depend upon the officers; and who so well able to help them as the doctor? To be spoken of, moreover, by a private soldier as "Dr. ——— of my regiment" implies a bond of union which the initiated will appreciate. In cantonments or a campaign, in peace or in war, in sickness or in health, the regimental surgeon, "Dr. ——— of our's," may occupy an enviable position—a position often fraught with some of the most interesting and touching recollections of a military career.

The "authorities" have responded to the request of the medical department for "unification," and what is the result? What does the abolition of relative military rank portend? That the days of the so-called army medical department—as essentially a *military* medical department with all its accompanying relative military advantages—are, if matters continue to progress in the direction to which they now point, numbered. The abolition of the regimental system was, I have always thought, a serious and short-sighted mistake; and the sooner that system is again adopted the better, I venture to say, for all concerned. It would be, moreover, the truest economy in the end.

I am, yours, &c.,
Chas. R. Francis, M.B.,
London. Surgeon-General.
